Preface

I can do all things through Christ, which strengtheneth me. Pilippians 4:13

I would like to thank everyone who helped me to finish this thesis effort. My first gratitude goes to my advisor, Maj. Keith Shomper. His patience, enthusiasm, and understanding of my situation guided me through this thesis. He showed me the way every time I encountered problems. My thesis committee, Lt. Col. Martin Stytz and Dr. Hartrum, provided me their positive energy and constant faith in my abilities. Their fairness and encouragement kept me going through the program.

I owe a sincere thanks to the ModSAF, EADSIM, and BATTLESIM developers those who met with me via the network or telephone. They gave me correct answers whenever I asked about the simulation. I wish to thank the many people at ModSAF reflector and Teledyne Brown User Support Group who quenched my thirst for knowledge.

I'm also indebted to a number of people who graciously extended their patience and friendship during the time I was writing this thesis. My hearty thanks goes to Doug Blake who devoted his time and effort to reviewing this thesis.

I also appreciate the cheering and encouragement of the Korean Officers who showed their interest and concern for my effort, and I want to express gratitude to the Christians of my church who offered a lot of prayers for me.

I dedicate this thesis to my family in gratitude for their eternal support, faith and love. I don't know how to thank my wife, Hae-Suk, who endure patiently everything until I graduated and my son Ji-Won who missed lots of fun with me. Finally, I send all my honor round to God who guided me, and also will guide me through my life before I face him.

Abstract

There exists a variety of simulation generation and analysis products which have differing purposes and functions designed to simulate a real military battlefield. Due to the particular purpose of each simulation, it is impractical to use one scenario of a simulation directly with another simulation without a translator since there is no standard scenario format. In the current environment, interoperability between simulations is becoming more important in large scale simulations and distributed exercises. The Scenario File Translator (SFT) provides an easy and accurate way to create a scenario from a heterogeneous simulation. The SFT can load and save the three research simulations: ModSAF, EADSIM, and BATTLESIM. It also defines the general transitional prototype (TP) which is the information most commonly used to create a mock battlefield computer simulation. System functionality is accessible through a graphical user interface (GUI). The four top-level steps to translate a scenario are loading a source scenario file, mapping to the TP, remapping the TP to a transitional target prototype, and saving the prototype as a target scenario file which a heterogeneous simulation use. Although this system was designed for three simulations, it can be applied to any other simulations by creating only two additional functions: one which maps the new scenario to the TP and another which remaps the TP into the transitional scenario protocol.

THE DEVELOPMENT
OF A SCENARIO TRANSLATOR
FOR DISTRIBUTED SIMULATIONS

I. Introduction

1.1 Background

Most people want maximum results with minimum investment in cost and time when doing a
work. Attempts to attain such results will continue and computer simulation is a good way to
accomplish it. Computer simulation is very useful when the real system does not exist or it is
expensive, time consuming, dangerous, or impossible to build [Neel87]. The effectiveness of
computer simulation in the military is especially apparent, since real combat conditions are
often costly to recreate and often dangerous. When we use computer simulation, we do not
have to fly many aircraft nor send hundreds of tanks to attack a target, furthermore we do not
have to maneuver thousands of soldiers to other places for training. Computer simulation also
allows testing of many scenarios in a short time so that we can measure which scenario is the
best model at a certain place.

To simulate a real battlefield, some preconditions should be solved, such as an
accurate terrain database, a precise description of strategy, and a stable network. High speed
computer networks and distributed simulation applications make possible computer
simulations for the military. Even though the opposing forces may be located far away, the
high speed communication network provides real time simulation as if each side is close at
hand. Thus the exerciser can develop fighting skills through mutual exercises. However, the
important thing here is that a standard communication protocol is necessary to implement the

distributed communication. For example, assume exercise *A* uses protocol *X* and exercise *B* uses protocol *Y*: how can exercise *A* know exercise *B* fires a missile, or is fired upon? Developing a well-defined standard protocol is as important as good simulation software. As a result, the Defense Advanced Research Projects Agency (DARPA, now called ARPA) made a standard communication protocol, which was named the Simulation Network (SIMNET). Between 1983 and 1989, ARPA successfully demonstrated the core technology for networking large numbers of manned, homogeneous simulators using SIMNET. Distributed Interactive Simulation (DIS) standards are being developed to provide industry wide standards that enable linking of heterogeneous systems. Since 1992, the DIS standards have been demonstrated numerous times. The demonstrated scenarios displayed maritime, air-to-air, ground-to-air, air-to-ground, and land operations. These demonstrations proved the viability of linking simulations of different types, based on different technologies, and built by different organizations [DIS 94].

The past few years have seen remarkable advances in DIS. The DIS environment allows military units from around the country to participate in mock training exercises without a large commitment of resources [Adam93]. As mentioned earlier, there now exists a variety of scenario generation and analysis products such as Integrated Eagle, Janus, CCTT (Close Combat Tactical Trainer), Modular Semi-Autonomous Forces (ModSAF), and Synthetic Theater of War (STOW). Each simulation has its differing purposes and functions. So after testing a scenario with different simulations, we can build better combat models and get more precise verification.

However, a basic problem still exists. Due to the particular purpose of each simulation, we cannot use one scenario of a simulation directly with another simulation without a translator since there is no standard scenario format. To test a new scenario, it is

impractical to manually recreate it to make it fit another simulation. In the current

environment, interoperability between simulations is becoming more important in large scale

simulations and distributed exercises. Since current scenarios can contain thousands of

entities, scenario setup and initialization can be quite laborious.

1.2 Problem Statement

There exist several ways to apply a battle scenario of one simulation to other simulation. The

most straight forward way is to recreate the scenario file in a format suitable for the other

simulation, but this is time consuming work and an ineffective. If we want to apply a

scenario to five different simulations, we need to make five versions of the same scenario for

each simulation. If we want to test 10 scenarios for these same five simulations, then 50

completely different scenarios are needed. There could be ten thousand entities in a scenario,

so it is not easy work to make a complete scenario. Making manual conversion of such

scenarios is inefficient. Another solution for these problems is a translation tool to

automatically convert scenarios from one simulation format to another. I propose to produce

a software tool that aids in the translation of scenario file formats so that scenarios developed

by different simulations can be run by each other. A well-defined translator will save time

and money, and it will provide the best way to test a scenario with different simulations.

1.3 Assumption

Most simulations have a specific purpose architecture. As the goal of each simulation is

different from others, the way to read or write a scenario file may also be different. For

example, the amount of munitions for a unit may be represented in one simulation, but not

another. So, translating one scenario format into a different format is not guaranteed to

preserve all information. That means some data which is not present in a target simulation can be lost while converting to another scenario. The important thing here is the conversion rate which shows how many entities are translated to the other simulation.

1.4 Approach

This section discusses some key decisions I used to accomplish this work. First of all, I had to choose a conversion method to translate one scenario to another. Based on this decision, I designed an intermediate format covering one scenario of each simulation. Then in the remainder of the section, I delineated detailed processes.

1.4.1 Determining Conversion Method

A problem with writing a generalized scenario translator is that the data structures used to initialize scenarios in different tools are very specialized. One way to solve this problem is to develop a tool which can map directly between any two simulations. This increases the conversion rate. This concept is depicted in Figure 1.1.
Figure 1.1 Direct Simulation Conversion

This concept is efficient when the number of simulations is small. However, whenever a new simulation is developed, it is necessary to write a new conversion routine. This routine translates the new scenario of the new simulation to each existing simulation: I also needed to create a routine that converts a scenario of an existing simulation to the new simulation. Assume there are currently N simulations. When a new simulation is developed, N routines are needed to map a scenario of the new simulator into the existing simulation, and another N routines are necessary to map the scenario of the existing simulations to the one of the new simulations. Thus a total of $2*N$ routines are needed.

Another way to do this is to do remap to a target simulation after mapping into an intermediate prototype. This is more efficient because it is not dependent on the number of existing simulations. This requires two routines: a routine that maps to the intermediate prototype, and a routine that remaps to the target scenario of the simulation. Thus only two routines are always needed, compared to the $2*N$ routines required using the previous method. Figure 1.2 shows this concept.
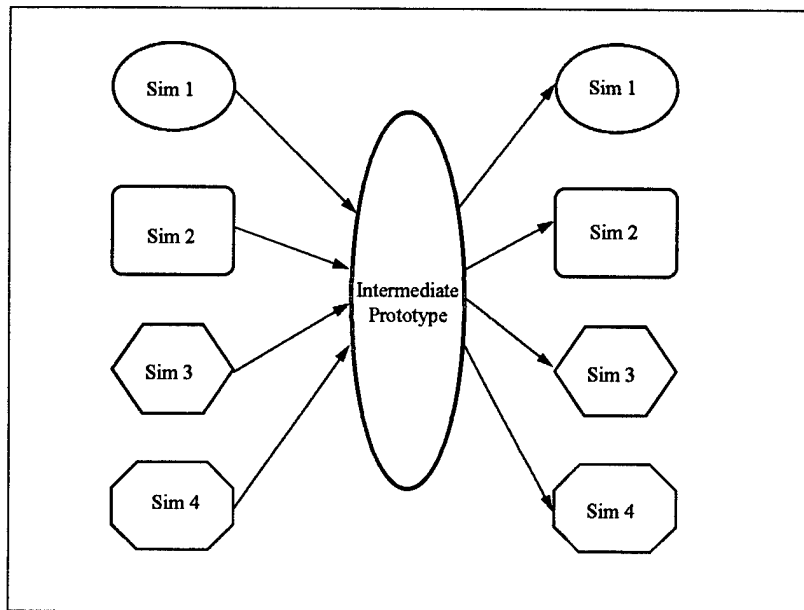

Figure 1.2 Conversion from Simulation to Intermediate Prototype

I propose that this translation be done in two steps. The first step is mapping a source scenario to an intermediate transitional prototype. The second step is saving the intermediate prototype to the target scenario format used to run target simulations.

1.4.2 Mapping to Transitional Prototype In order to develop a reasonable mapping, I first began with a comprehensive survey of the three target research simulations: ModSAF, EADSIM, and BATTLESIM. Furthermore, I had organized the survey as the following set of tasks.

- Review of Semi-Automated Forces (SAF)

  First, I reviewed the history of SAF technology and current research efforts in the field. That review gave me a basic knowledge of the simulations.

- Survey of current simulations

  Next, I investigated each simulation's basic architecture and scenario's formation. It was beneficial for me to understand what things were common and what points were unique.

- Finding the Transitional Format

  Finding the transitional format was the most important part of this research. By choosing a well-designed transitional format, I could make a more generic program. The way to find an intermediate transitional prototype that suits this concept is either to select a protocol among these currently developed or to define a new protocol fitting the above concept. A more detailed discussion of this topic appears in Section 3.3.1.

- Build the Comprehensive Table

  Following these steps, I composed a table suitable to compare each simulation. This table gave me the insight into what data are in common and which data structure is more efficient to translate a scenario.

1.4.3 Remapping to Target Scenario

The remapping step to a target scenario using the comparison table was the index of performance for this research effort. As I mentioned in Section 1.3, it was unrealistic to expect 100 % conversion; however, a "close" scenario was likely, and it was the goal of this research to determine how "close" a conversion the transitional prototype could support. This goal was implemented through the next two steps.

- Find the common data between target scenario and the transitional prototype.

- Save as a new scenario file which can be read by a target simulation.

1.5 Thesis Overview

This thesis is divided into six chapters. Chapter Two presents the background material on Advance Distributed Simulation, and DIS and Computer Generated Forces (CGF) or SAFs. Chapter Three focuses on the requirements definition and analysis process and its translation into a system design. Chapter Four discusses implementation of the system and describes how it works. Chapter Five summarizes the results and illustrates several test cases. Finally, Chapter Six provides recommendations for future work and the conclusion.

II. Background and Literature Review

2.1 Introduction

This chapter summarizes the work in the two major research areas that is relevant to my thesis effort. Since the primary purpose of this thesis was to create a scenario translation tool, I completed a survey of the enabling and supporting technology in that field. The first section provides a historical background how DIS was evolved, and the next section lays the foundation for understanding the important concepts in military simulation. Finally, the last section discusses three of the simulations recently developed – ModSAF, EADSIM and BATTLESIM – and focuses on how each simulation works and what are the differences among them.

2.2 Historical Background

To date, various research efforts have focused on developing war game simulations which have a particular ability for the given research. New simulations with new abilities are created one after another, and existing simulations are upgraded to be more accurate and realistic. The one point that all simulations have in common is standardization through the network for sharing data. This standardization has been accomplished using DIS.

DIS had been started in 1989 when ARPA initiated a program to enhance the Simulation Network (SIMNET) program. SIMNET was developed for building a cross-country network of interactive combat simulators [Pope91]. Its demonstration of approximately 250 simulators successfully showed the possibilities of distributed simulation. SIMNET technology is still used today to train U.S. Army tank teams around the country.

DIS is a set of protocols that carry messages about entities and events through a network. When a network provides reasonably low latency (100 to 300 milliseconds) and low

latency variance, the characteristics of the network present few problems to building a virtual world that is separated by thousands of miles in the real world [DIS94]. One important aspect of DIS development is the effort to recognize DIS as an international standard for distributed simulation. Thus, the DIS standard was submitted and approved by the Institute of Electrical and Electronic Engineers (IEEE) as IEEE standard 1278. Following IEEE approval, the standard was submitted to the appropriate international agencies for international standard approval. This is useful, since it promotes cooperation among the U.S. and its allies in the field of simulation [McDo91].

2.3 Military Simulation Technology

2.3.1 Distributed Interactive Simulation (DIS)

2.3.1.1 Concept DIS is an interconnected, time-coherent simulation system which creates a distributed, interactive environment using the IEEE 1278 protocol [Siko95]. DIS simulators exchange information in formatted messages called Protocol Data Units (PDUs). These PDUs provide data for the management and control of a DIS exercise and provide data concerning simulated entity states and the types of entity interactions that take place in a DIS exercise. It is possible for geographically separated simulators to interact with each other via network communications by the DIS standard [IST94]. DIS is designed for linking the interactive, free play activities of people in operational exercises to represent a time and space coherent synthetic world environment. This environment is created through real-time exchange of data units between distributed, computationally autonomous simulation applications in the form of simulation, simulators, and instrumented equipment interconnected through standard computer communicative services. The meaning of "distributed" is that no single computer controls the simulations. Rather, each local computer is responsible for sending local copies of common terrain and models

(e.g., tanks, fighters, and naval vessels), and remote entities based on incoming PDU messages. Local applications are required to send entity updated entity states when dead-reckoning thresholds are exceeded or five seconds have elapsed [Gard93, Shea92]. Entities' positions and orientations are predictable by using the Dead Reckoning algorithm so that the number of transmitted PDUs can be kept as low as possible. This increases the scale of the exercise and reduces network communications traffic from a single simulator [Gard93]. Dead Reckoning is an important algorithm as one of the basic concepts underlying the DIS architecture. It also diminishes the computational processing associated with receipt of each new PDU because fewer PDUs are received [Harv91].

2.3.1.2 DIS Objectives   Principles of the emerging DIS standards and their applications are introduced in this section. Basic architectural concepts include [IST94]:

- No central computer controls the entire simulation exercise,

- Autonomous simulation applications are responsible for maintaining the state of one or more simulation entities,

- A standard protocol is used for communicating "ground truth" data,

- Changes in the state of an entity are communicated by simulation applications,

- Perception of events or other entities is determined by the receiving application, and

- Dead reckoning algorithms are used to reduce communications processing.

   A definition of each of these concepts is provided in the proposed IEEE draft in reference [IST93].

2.3.1.3 DIS PDUs   DIS currently defines 27 different PDUs. A complete description of each of these PDUs can be found in reference [IST94] and can be grouped into the following general categories:

- Entity Information/Interaction,

- Warfare,

- Logistics,

- Simulation Management,

- Distributed Emission Regeneration, and

- Radio Communications.

Only 12 of these 27 PDUs have a fixed length. Each of the remaining PDUs has a variable length dependent upon many factors including numbers of articulated parts, numbers and types of emitters, length of audio transmissions, and amount of data.

Table 2.1 [IST94] depicts the entity state PDU as an example of the content and format of the DIS PDUs.

2.3.2 Advanced Distributed Simulation (ADS) Computer simulation has been used by military analysts in various aspects since the 1950s, especially in mock battle areas. At the beginning, it had very limited scope due to the vastness of the battle and the complexity of the simulated war, which also made it difficult to use and to satisfy the users. The development of larger mainframe computers in the 1960s resulted in enlarged storage capacity and greater processing speed allowing better digitized terrain and larger scenarios than before. By the 1980s, the capabilities of computer-based simulations had really expanded with the advent of microprocessor chips, high speed data communication links, larger mass storage devices, and flexible, detailed displays. all at low cost. Today, the simulated battlefield can depict more accurately real-time war games because of continually improving computer capabilities. As the SIMNET and DIS demonstration showed, it is possible to have different simulated battlefields at dispersed geographic locations working together. The new capabilities, such as high-speed communication networks, common network interface/translation devices, and emerging standard data protocols, have allowed a time-coherent, interactive synthetic

environment where computer simulation, real equipment and systems, and humans work together in synthetic battlefields for training, system development, testing, and force assessment. This synthetic environment through geographically distributed and using potentially dissimilar simulation hardware and software is a technology area named Advanced Distributed Simulation (ADS) [Siko95].

There are many goals in ADS. The main goal is to create a synthetic world distributed over a global network, which is realistically populated with: high resolution, dynamic terrain; tactically significant environmental effects; individual combatants and weapon platforms [Garr95]. Three simulation types including these main components are discussed below. The first one is *'live simulation'* in which real people operate real systems in actual operational conditions. For example, an operational test of the F-22 in an electronic combat environment in Nevada is an example of a live simulation. The second one is *'virtual simulation'* in which real people operate simulated systems. An example is a testbed such as Advance Research Project Agency's (ARPA) Simulation Network (SIMNET). However, the most important and capable examples of this type are represented by Distributed Interactive Simulation (DIS) systems. Finally, those simulations in which simulated people operate simulated systems are called *'constructive simulations'*. Computer generated forces such as Modular Semi-Automated Forces (ModSAF) are good examples of this type of simulation.

One of the important functions of ADS is to 'talk to and understand' what other connected simulations are doing and what their simulated elements are doing. If the simulations which compose a specific ADS configuration are all of the same type, scope, and data structure, the communications interface between them is relatively straight-forward. However, most simulations in an ADS have different scopes and data structures. So a common language (or protocol) is necessary to enable communication with all connected simulations. The most widely recognized and most comprehensive effort to define an ADS standard simulation protocol is the DIS protocol. Development of this protocol occurs as a cooperative effort by government and industry through Forms called the Distributed Interactive Simulation Workshops [Siko95].

2.3.3 Computer Generated Forces (CGF) When the Army Modeling and Simulation Master Plan was published in 1994, it named 20 areas for consideration in the Army modeling and simulation community. The Master Plan defined the implementing software standards across the modeling community and encouraged standards for development through the establishment of "teaming arrangements" and "consensus building" within the Army modeling community. CGF is the one of those areas. CGF Systems originated in the SIMNET environment in the mid 1980s. Their initial use was to provide a set of threat vehicles and live friendly forces to train personnel in the SIMNET simulators. Since 1990, CGF systems have been used in other ways, providing both friendly and threat forces in virtual experimentation environment. These CGF-based virtual battles have been interfaced with sensor simulators (J-STARS) and live personnel in the command and control (C2) network making decisions on interdiction of deep targets. The following list is a minimal set of objectives for any CGF system as a "standard" [Pick95]:

- The CGF system must be useful to all three applications: training, advanced technology demonstration, and analysis. This objective implies specific requirements such as:
  - Ability for man-in-loop simulators to interface at any echelon.
  - Ability to interface with live systems at any echelon
  - Ability to run real-time and, for analytic applications, faster than real-time.
  - Ability to interface with constructive models in the constructive+virtual environment.

- The CGF system must be DIS compatible and also have the ability to operate across both local and wide area nets.

- The CGF system must represent the battle from Corps to individual vehicle.

- The CGF system must interface with other Service models in a Joint exercise.

- The number of operators in the CGF system must be minimal.

- The structures and data bases simulating the physical and cognitive/tactical behaviors of the vehicles, personnel and units must be modular and easily isolated for Verification, Validation & Accreditation (VV&A).

For the architectural development of any CGF system, the design of certain components are needed, which provide the simulation with the ability to represent the physical

environment in which the battle will take place, to represent the combatants themselves and to represent a C2 structure for organizing the individual combatants into units and as a single fighting force. The CGF system also demands the development of services supporting a distributed simulation. The goals for depicting a CGF simulated environment are to represent the individual vehicular commander to perform METT-T (Mission, Enemy, Troops, Terrain and Time) activities, to represent the effects of weather, dynamic changes in terrain, and battlefield haze and smoke.

2.4 Distributed Simulations

This section gives a brief synopsis of some SAF simulations that have been recently developed such as ModSAF, EADSIM and BATTLESIM.

2.4.1 Modular Semi-Automated Forces (ModSAF)

ModSAF is the successor to the SIMNET and ODIN Semi-Automated Forces systems. ModSAF 1.0 was released in December 1993 following the development of the ModSAF architecture in the spring of 1992 under sponsorship by ARPA/ASTRO and STRICOM [Cour95]. ModSAF is a combat simulation that supports DIS. It lets us create and control combat entities on a simulated battlefield. These entities replicate the outward behavior of their component vehicle and weapon systems to a level of realism sufficient for training and combat development [ADST95]. Figure 2.1 shows an actual ModSAF simulated battlefield.

2.4.1.1 ModSAF Architecture
There are three components in the ModSAF architecture: (1) SAFstation, (2) SAFsim, and (3) Logger. These components are typically run on separate computers over a network; however, the SAFsim and SAFstation can run on
Figure 2.1. ModSAF simulated battlefield

the same computer. The components communicate physical battlefield state and events

among themselves through the simulation (DIS) protocol and command, control, and system

information through the Persistent Object (PO) protocol [ADST95].

Figure 2.2 shows the SAFstation and SAFsim components communicating over a

network via PO and simulation packets that are marked with the same exercise ID [ADST95].

SAFsim and SAFstation communicate command, control, and system information via PO

packets for bundling graphic, unit, model parameter, task, task frame, and exercise data.

When we create objects on the SAFstation, PO packets which are representing the state of

each object are projected onto the network so that the objects they represent can be simulated

by the SAFsim. SAFsim and SAFstation communicate physical battlefield state and events

between themselves via simulation packets for entity state, impact, collision, fire,

initialization, radar, and weather data [ADST95].
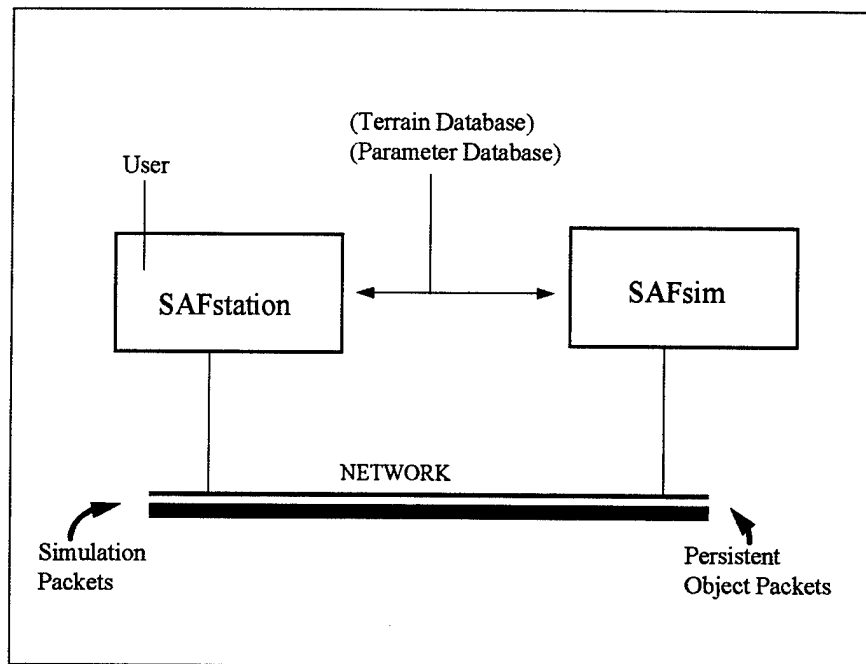

Figure 2.2 SAFstation and SAFsim components of ModSAF

The Parameter Database contains the modeling parameters used in the construction of the ModSAF system. This set of parameter files allows modification of the ModSAF system without further computer programming. Both the SAFstation and the SAFsim components have access to a Terrain Database. The SAFsim simulates objects known as ModSAF 'entities' (such as planes and tanks) which can behave autonomously. When a SAFsim simulates a unit, the SAFsim not only creates the entities in the unit, it also builds a structure corresponding to the unit hierarchy.

2.4.1.2 Scenario File organization   ModSAF uses only one file to present a battle scenario that might have hundreds or thousands of entities. ModSAF 2.1 defines 21 classes to describe these entities. A scenario file consists of two parts: a header part and an entity part. The

header part includes some global data such as version number, number of objects and number of entries. The rest of a scenario file is all about these entries. ModSAF reads a scenario file sequentially according to this number of entries. An entity part also consists of two parts: the file entry part and the class part. The important data of the file entry part is the size of class which follows the entry part. Table 2.2 shows this data structure of a scenario file. As each class from the scenario file is read, one large battle scenario is created.

Table 2.2 Data Structure of ModSAF scenario file

Name		Data of Interest
Header Part		File Format Protocol Version Database Version Number of Objects Number of Entities
0	File Entry	Serial Number Variant Size
	Class	
1	File Entry	
	Class	
continue by number of objects in header part		

2.4.2 Extended Air Defense Simulation (EADSIM)

EADSIM is a simulation of air and missile warfare used for scenarios ranging from few-on-few to many-on-many. Each platform (such as a fighter aircraft) is individually modeled and the interaction among the platforms is also individually modeled. EADSIM also models the Command and Control (C2) decision processes and the communications among the platforms on a message-by-message basis. Intelligence gathering is explicitly modeled as is the

2 - 11

intelligence information used in both offensive and defensive operations [TBE95]. The

general areas modeled are: air defense, offensive air operations, attack operations, multi-stage

ballistic missiles, air breathers, sensors, jammers, satellites, early warning, generic

noncombatants, communications, electronic warfare, terrain, weaponry, and areas of interest.

Figure 2.3 depicts an EADSIM Scenario playback.
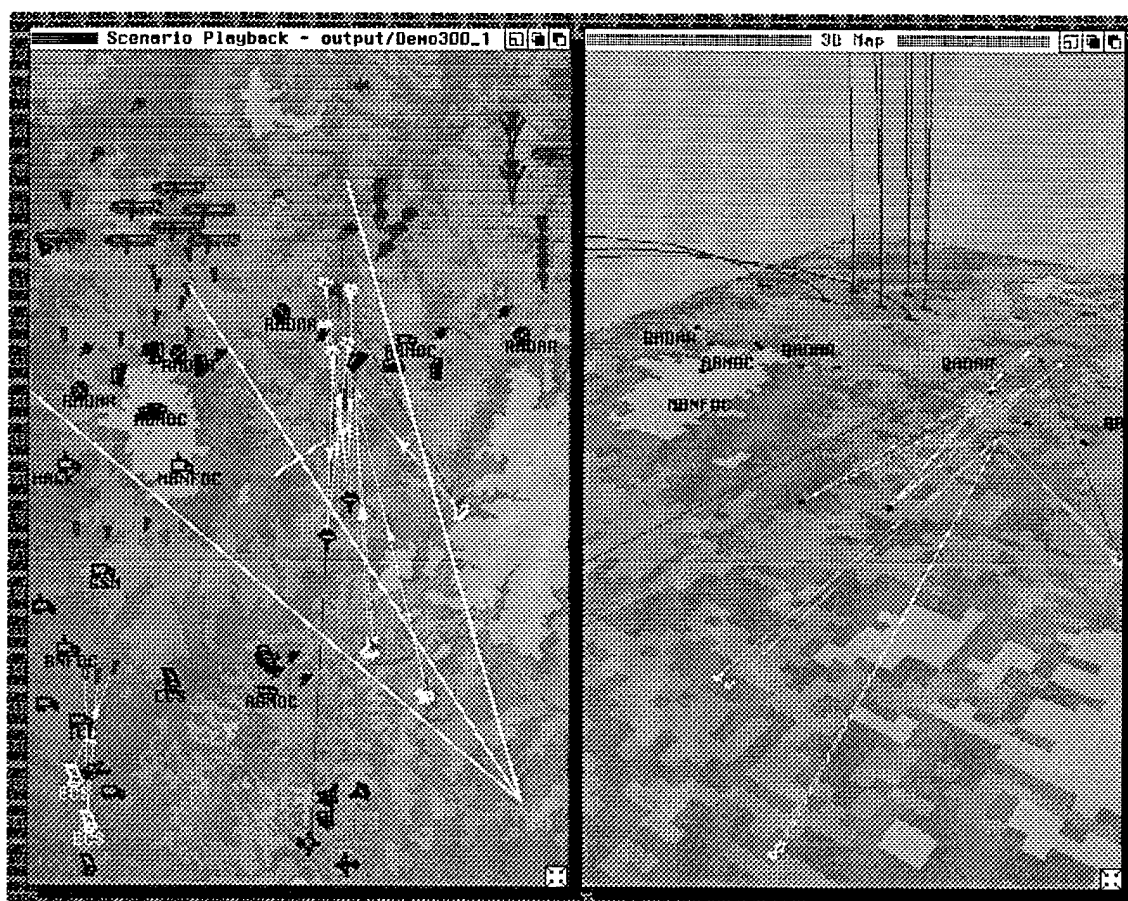

Figure 2.3 EADSIM Scenario Playback

2.4.2.1 EADSIM Architecture   The EADSIM model consists of numerous processes and

process applications which perform three basic functions: simulation setup, execution of a

scenario, and post-processing and analysis. The simulation setup and post-processing and

analysis tools are run on a graphic window manager which provides the primary user

interface. The execution of a scenario is performed by a set of run-time models running in a

multi-process configuration. Figure 2.4 shows the processes and applications making up each

of these areas [TBE95].
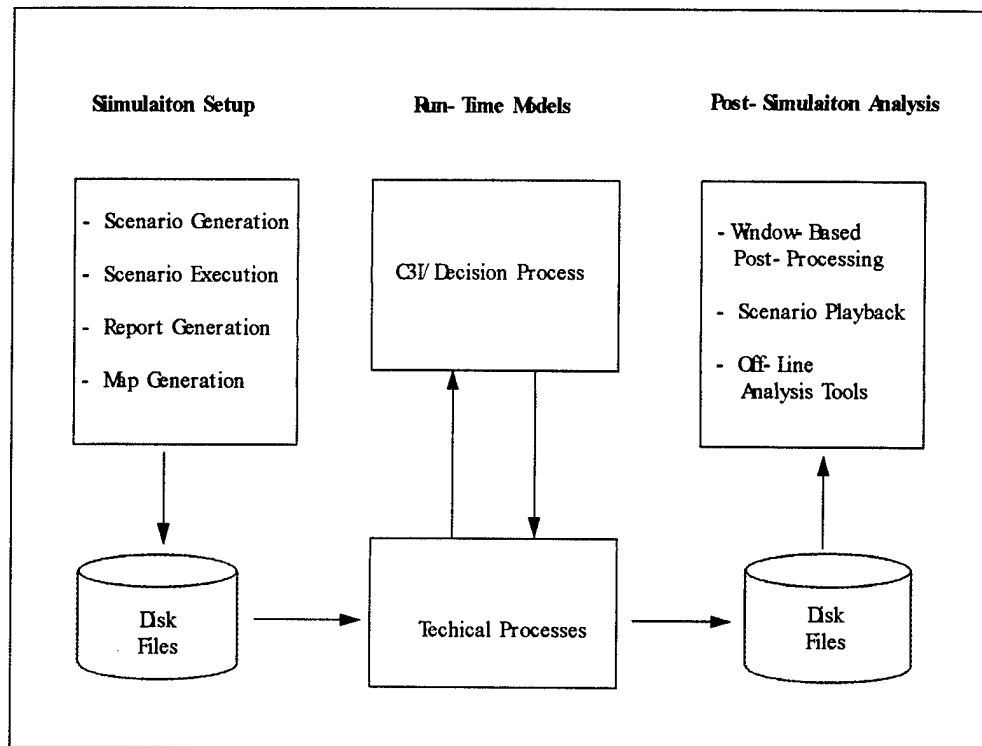

Figure 2.4 EADSIM Model Processes and Applications

2.4.2.2 Scenario File Organization A scenario file is made by EADSIM's Scenario

Generation. The data of the scenario is organized in a hierarchical structure on which each

level of the hierarchy is built on lower levels. The lowest level in the hierarchy is the

elements. Combinations of these individual component elements are then used to organize

System Elements that are deployed to form Platforms. Groupings of Platforms are built into

Laydowns, where the Platforms in the Laydowns are interconnected with Networks which also

use the Protocol elements. This Platform level corresponds to entities which most people know. Areas of Interest (AOIs) can be created and associated with both Platforms and Networks. The Map specification forms the geographic basis for the scenario. The scenario is then a further combination of all of the lower level data [TBE95]. Figure 2.5 [TBE95] is a diagram representing the data organization.

A HIERARCHY OF DATA ORGANIZES AND EXPEDITES THE SPECIFICATION OF A SCENARIO

- SCENARIOS ARE THEN A FURTHER COMBINATION OF LOWER LEVEL DATA

- SYSTEMS ARE DEPLOYED

- ELEMENTS COMBINE TO MAKE SYSTEM ELEMENTS

- INDIVIDUAL COMPONENTS ARE SPECIFIED AS ELEMENTS

Figure 2.5 EADSIM Scenario Composition

2.4.3 Battlefield Simulation (BATTLESIM)

BATTLESIM is one of the Air Force Institute of Technology (AFIT) Parallel Discrete Event Simulation (PDES) research efforts. The primary discrete event simulation (DES) environments available for use at AFIT are Battlefield Simulation (BATTLESIM), the Parallel Ada Simulation Environment (PASE), Very High Speed Integrated Circuit (VHSIC)

Hardware Description Language (VHDL) Simulation (VSIM), and Queuing Model

Simulation (QUEUESIM). These environments have evolved over the course of the AFIT

parallel simulation research program to employ parallelism using the Chandy-Misra

conservative synchronization approach as implemented in the SPECTRUM (Simulation

Protocol Evaluation Testbed using Reusable Models) host manager [Hill94]. DES is an

event-driven simulation approach in which the simulation changes state upon event execution

[Hill94]. PDES is usually viewed as the decomposition of a single DES program into logical

units that can be executed concurrently on distributed processing architectures [Fuji93].

BATTLESIM is integrated with TCHSIM (Thomas C Hartrum Simulation) which is a

collection of general DES mechanisms and services and with SPECTRUM which is a parallel

simulation protocol testbed based on the LP (Logical Process) model.

2.4.3.1 BATTLESIM Architecture   BATTLESIM is a battlefield simulation PDES

application supported by some lower-level components. Figure 2.6 [Hill94] shows the major

BATTLESIM, TCHSIM, and SPECTRUM components in the context of the general DES

architecture. The lowest level in the component is the AFIT version of SPECTRUM that

provides the host machine process management and communication services. The

SPECTRUM supports the TCHSIM as it manages the creation and communication between

each LP. The processing which supports TCHSIM contains both an input/output message

handler and synchronization logic for inter-LP message flow control. TCHSIM is an object-

oriented collection of structures and operations that provide basic simulation services. It also

is simulation kernel, providing a simulation clock, a NEQ (Next Event Queue), a top-level

event dispatcher, and structural definitions for simulation events and relationship mappings

[Hill94].

2.4.3.2 Scenario File Organization   A scenario file of BATTLESIM generally consists of

two parts. The first part is a Header part which declares global data for the scenario file.

The second part is the Entity part that can be repeated many times. Table 2.3 shows the

organization of a scenario file. In the Entity part, there are several other repeated Entity

parts, as many as defined by the number of each part.

2.5 *Summary*

This chapter discussed the background on Distributed Interactive Simulation (DIS) and a new technology area, Advance Distributed Simulation (ADS), as well as Computer Generated Forces. It also provided a brief synopses of some SAF simulations which were recently developed and available for experimentation at AFIT. Specifically, this chapter addressed how each simulation works and what are the differences among them. It is important to first understand the architecture of each simulation and the organization of their scenario files before we can design a process for translating between these formats.

III. System Requirements and Design

3.1 Introduction

This chapter describes the requirements for the Scenario Translator and their incorporation into the system design. I specified the definition of several essential words in my thesis work area, and delineated General objectives of the system design in the requirements section. Design details follow in the design section. General requirements are introduced in the discussion of the definition phase. The overall requirements formed the basis for system design, while the detailed requirements translated into specific system capabilities.

3.2 Definitions

We use the following definitions throughout this document as shown below:

- Simulation: a method for implementing a model over time
- Scenario: a sequence of events or a possible course of action
- Scenario File: a file which stores a scenario
- Source Scenario: a scenario file which will be translated to another format
- Target Scenario: a scenario file which is produced by a translation tool
- Source Simulation: a computer simulation which operates a source scenario
- Target Simulation: a computer simulation which operates a target scenario
- Transitional Prototype (TP): an intermediate prototype to translate a source scenario to a target scenario
- Transitional Source Scenario Prototype: a data structure in computer memory which stores a source scenario
- Transitional Target Scenario Prototype: a data structure in computer memory which stores a target scenario
- Scenario File Translator (SFT): a translation program that converts a source scenario to a target scenario

3.3 Requirements

The requirements are divided into five main areas:

- Defining a Transitional Prototype,

- Loading a source scenario of a source simulation

- Mapping the source scenario to the TP,

- Remapping the TP to a transitional target scenario prototype, and

- Saving the transitional target scenario prototype as a target scenario for a target simulation.

The first requirement, defining a TP, is the most important part of my work because a good prototype can accommodate common simulations. This makes the system extensible and reusable. The second requirement, loading a source scenario of a source simulation, stems from the necessity to convert a battle scenario to one which can be run by another simulation. The third goal, mapping the source scenario to the TP, is also important since it determines how much information can be translated from the original battle scenario to another simulation. Fourth, remapping the TP to a transitional target scenario prototype is a necessary step to convert a source scenario to a target scenario. Finally, saving a transitional target scenario prototype is significant since all my effort is worthless if the target simulation cannot read the target scenario and work fine.

3.3.1 Defining a Transitional Prototype

3.3.1.1 Insufficiency of DIS PDU
As mentioned previously, creating a well-defined prototype is the most important part of this work. Initially, it was desired to select a widely-used prototype. Such a selection would provide better accuracy in translating simulation

scenarios as well as save time by precluding the necessity of defining a new prototype. For these reasons, it was decided to use DIS PDUs to define the TP, since most simulations either support or will support that protocol. DIS PDUs send current events over the network, so other heterogeneous simulations can reorganize the scenario by receiving these PDUs. It also provides for the simulation to predict the direction of an entity by using the dead reckoning algorithms. Unfortunately, DIS PDUs do not provide certain critical pieces of information including the first position of an entity, amount of munitions, mission, etc. Thus, although it is possible to ascertain where an entity is going, it is not possible to determine where it came from, why it is on its current heading, or what its actions will be when it arrives at its objective. Table 3.1 provides comparison between the type of information which each simulation has and its matching data in DIS PDUs.

Table 3.1 Matching Comparison between Simulation Scenarios and DIS

Simulation Name	Number of Variables			DIS Matching Number	Percentage
	Header	Entity	Subtotal		
ModSAF	11	271	282	17	6.0
EADSIM	167	215	382	13	3.4
BATTLESIM	15	51	66	17	25.8
Total	193	537	730	47	6.4

3.3.1.2 Defining a New Prototype The previously-mentioned limitations of DIS PDUs required defining a new prototype which contains the static and scenario-wide information missing in the DIS PDUs. In order to develop a new prototype, it is first necessary to define those piece of information which form the basic scenario. First of all, the scenario entity and the mission to be performed by the entity are the basic compositions of a scenario. There are

thousands of different entity types. For example, an entity can be defined as a platoon or as ten army divisions. It could be something as small as an anti-personnel mine or as large as an airplane, tank, missile base, or aircraft carrier. An entity also has its own initial position, mission, armed capacity, orientation and velocity as well as entity ID and entity name. Items such as entity ID are especially important because they allow for unique identification. The capacity of their armament is also quite different, just as the amount and kind of munitions that can be loaded on an F-16 may vary. However, the entities themselves do not comprise the entire scenario. Only after each entity is given a mission is a scenario brought to life. Missions also depend on the types of entities. Missions for ground units are quite different than those for air units. Thus, both entity and mission must be described when defining a new prototype. Furthermore, the effect of the environment cannot be neglected in composing a scenario. Mountains, buildings and weather conditions must be considered since both sides are not fighting on a plain where everybody can see each other directly. Finally, not-readily-quantifiable items such as willingness to fight, morale, and experience can also affect a scenario's outcome and are worth consideration. A more detailed discussion of this topic appears in Section 3.3.3, Transitional File Specification.

3.3.2 Loading a Source Scenario The first step to convert one battle scenario to another is to read the source scenario. This is accomplished in most simulations via embedded procedures. Since the objective of this work was to develop a translator program, it was necessary to separate the scenario initialization code that simply reads the source scenario. This has the benefit of greatly simplifying the SFT's reader. It is reasonable that the resulting data by the loading system should be same as the one by a distributed simulation. In chapter Four, Implementation, I discuss advantages and disadvantages with using the source

simulation's reading module directly or creating a new simple reading module to load a scenario.

3.3.3 Mapping to a Transitional Prototype   As described in Section 1.3, using the intermediate format is efficient because it is not dependent on the number of existing simulations. As we can see in Figure 3.1, only two routines are needed even when a new simulation is developed.
Figure 3.1 Conversion using an Intermediate Format

Matching each simulation to the TP guarantees greater extensibility than a direct matching of each simulation to one another as mentioned in Section 1.4, Approach. When converting to the TP, it is important that the mapping should be performed to the most general and acceptable data which can be remapped to any simulation. The position of an entity is a good example. The position of an entity can vary between simulations, because of terrain differences and relative coordinates used by each simulation. If the coordinates of the entity

are saved as they are when mapping to the TP, it may cause confusion in other simulations. Additionally, unless the defined TP covers all of the information contained in a source scenario, parts of the scenario may become lost.

For example, there are two simulations, each of which has a different purpose. Denoting the scenario files associated with each simulation as *S1* and *S2*, respectively, we want to translate *S1* to *S2*. *S1* is therefore a source scenario while *S2* is a target scenario. After mapping *S1* to the TP, the mapped area is shown by ▤ in Figure 3.2. This results in the area shown as ▨ becoming lost. When we define the more general intermediate prototype, the mapped area (▤ area) becomes larger and the lost data (▨ area) becomes smaller.
Figure 3.2 Mapped and Unmapped Area into Intermediate Format

3.3.4 Remapping to a Transitional Target Scenario Prototype   After mapping a source scenario to the intermediate format, TP, it is ready to be subsequently changed to any format. When we wanted to change scenario *S1* to scenario *S2* in the previous example, it was

necessary to convert the mapped area to a writable structure to save as scenario *S2*, in other words, to map the common area between *S1* and TP to a common area between TP and *S2*. In the mapped area in the previous example, the part which is common between the intermediate format and *S2* is the area shown as ▦ in the Figure 3.3.
Figure 3.3 Common Area Between Intermediate Format and Target Scenario

Of prime importance in the file creation is to consider data which is defined in the TP, but cannot be re-mapped to the target scenario. In most cases, this data affects the other scenario in a limited manner since this area is information for only the target scenario such as host computer name, directory path, set-up data for background color, image type, and entity icon format. Thus, the loss of the most data in this area is acceptable. However, there still exists some critical data of a target scenario which is not represented in the source scenario. This results in lost data (▨ area in Figure 3.4). The problem of undefined can be mitigated by mapping to commonly used default values. For example, assume a scenario needs the angle of the radar beam of an aircraft, but that information is not available. In this instance,

that information can be replaced by the common average angle of the radar beam, a value which is commonly known and can be readily approximated.
Figure 3.4 Unrepresented Area In a Target Scenario

3.3.5 Saving the Transitional Target Scenario Prototype   After mapping the intermediate format, TP, to a transitional target scenario prototype, a new scenario file is created. The newly saved scenario file should be readable by the target simulation. Here we also must determine whether to use an existing output module within the target simulation's code or to develop a new module. Chapter Four discusses this issue in more detail.

3.4 Design

3.4.1 Hardware Specification   I designed this program to be machine independent. Platforms used in testing were the SGI and Sun Workstations.

3.4.2 Software Specification

3.4.2.1 General Organization Figure 3.5 shows the general organization and operation process of this program. The Translator, the core of this program, loads the source scenario to be translated, maps to the TP, and then saves as a target scenario. The TP can either be stored to disk for future use or immediately converted to another target scenario.
Figure 3.5 Translator General Diagram

3.4.2.2 User Interface I designed a Graphics User Interface (GUI) using the Motif library to provide a convenient interface for the user. In the instance where the Motif library is not available on the machine of implementation, I also made the program with a command line interface.

3 - 9

3.4.2.3 Object Diagram The Figure 3.6 shows the object diagram of the Scenario File

Translator. This top-level diagram also shows the unique object classes identified for the

SFT based on the decomposition of system requirements. The seven objects within the SFT

are: the Translator object, the Scenario File object, the Prototype object, the Transitional File

object, the Entity object, the Character object, and the Mission object. The Simulation object

is composed of the Scenario File object, the Terrain object, and the Initial Setting object.

Since the SFT only interfaces with the Scenario File object, only this object is important to

my design. The Scenario File object consists of the Entity objects, which have their own

characters and missions as mentioned in Section 3.2.1.2, Defining a New Transitional

Prototype.

The Translator object contains the Prototype and Transitional File objects and uses

the Scenario File object to load and save the TP. To map from the source scenario to a target

scenario, the Translator object loads into memory each simulation transitional format. The

reason why the transitional scenario prototype is needed is discussed in Section 3.4.4,

Transitional Target Scenario Prototype. After the Translator loads the source scenario, it

maps the scenario to the Prototype object. The Translator can save the scenario as either the

target scenario or the Transitional File format.

To save to the target scenario, two steps are needed. The first step is to map the TP

to the transitional target scenario prototype, then the Translator program saves the TP as a

target scenario, which the target simulation can then use.
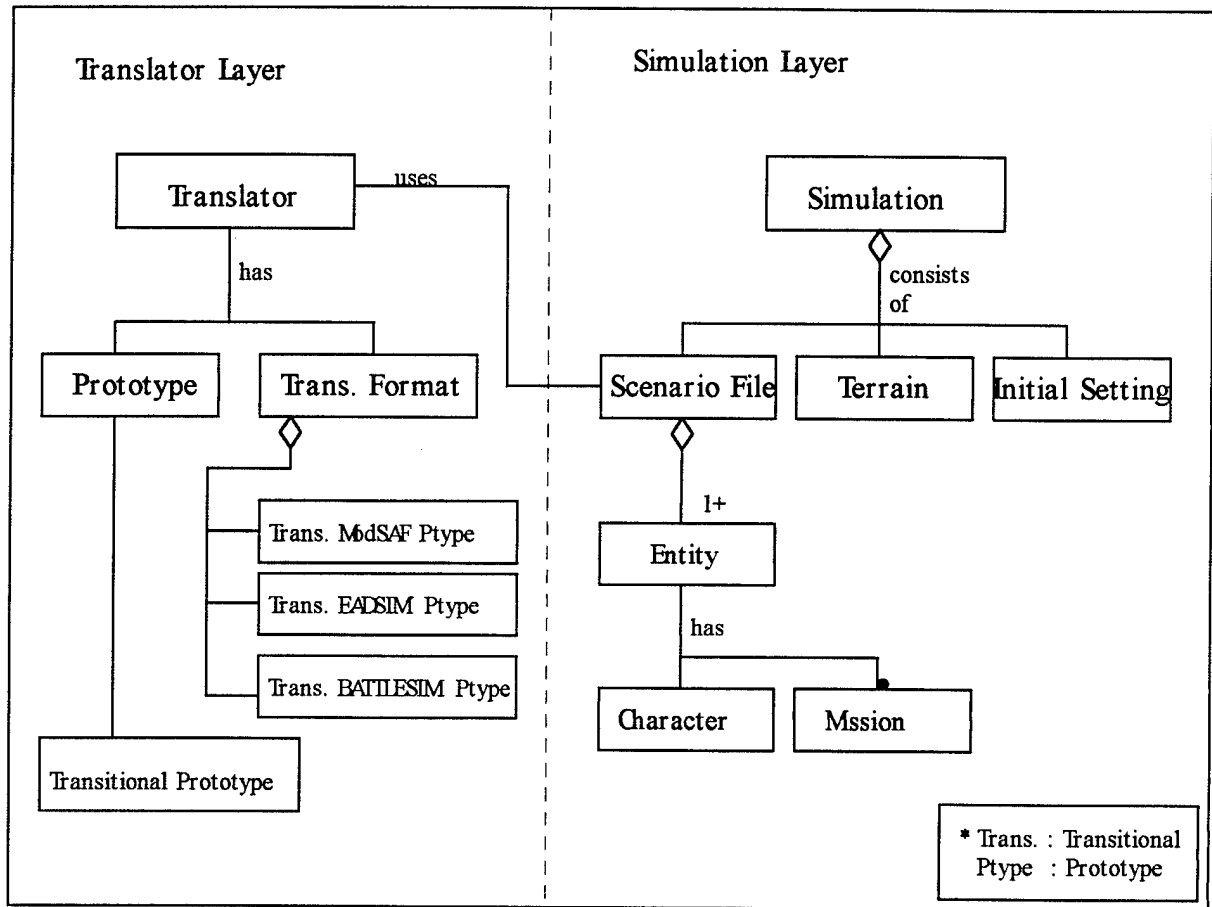

Figure 3.6 Scenario Translator Object Diagram

3.4.3 Transitional Prototype Requirements

3.4.3.1 Ideal Prototype The ideal format for the TP is a set of information which covers all

data for all simulations including those which are not currently supported by the translator.

Clearly, this is not practical; therefore, including parts generally common to all simulation

scenarios is advisable.

3.4.3.2 Proposed Prototype The basic essential composition of a scenario, the

characteristics and missions of the entities, have to be describable in any format I propose.

Extensibility of the translator is promoted when the way to address the entity and mission is

accomplished through general methods. Figure 3.7 shows the relationship among ModSAF, EADSIM, BATTLESIM, and the TP.
Figure 3.7 Relationship between Simulations and Suggested Prototype

The overlapping parts in the Figure 3.7 indicate the common parts between any two simulations. The size of each rhombus and a circle in the figure does not present the actual file size of each scenario and the intermediate format, respectively. The center part where the three rhombuses overlap is the most common information which is present in all three simulations. As is evident in the figure, some data can be lost in mapping from a scenario into the TP. In this case the default values should be matched to the undefined part in the TP during mapping from the TP to a target scenario. How I accomplished this is discussed in the following section.

3.4.4 Transitional Scenario Prototype Specification

When loading a source scenario, it is desirable to read all information contained in the using source simulation's original data structures. Thus the transitional source scenario prototype are designed to read all information whether needed by another simulation or not to minimize data loss. The rest of this section describes the data structure of the source scenarios and tells how these structures influenced the design of the transitional data structure. The reader may refer to Appendix A for more details about each transitional source scenario prototype.

3.4.4.1 ModSAF

As mentioned in section 2.4.1.2, a ModSAF scenario file is divided into two sections: a Header part and a Class part. Figure 3.8 illustrates the top-level data structure of a ModSAF scenario file.

Transitional ModSAF Scenario Prototype

Figure 3.8 Transitional ModSAF Scenario Prototype

3.4.4.2 EADSIM

It is not possible to create a scenario by reading only one file in EADSIM because a complete scenario is contained in several different files. The important files among them are the laydown file which stores the platforms describing each entity, and the scenario file which describes the initial conditions and the name of laydowns. Figure 3.9, Figure 3.10 and Figure 3.11 shows the Prototypes for a 'scenario file', a 'laydown file', and a platform.

3.4.4.4 Transitional Prototype Table 3.2 shows a data structure of the TP. Each structure consists of variables that have same character. The column 'Type' describes the variable format of the structure, and the enumeration type is described in Appendix B. The variable name 'Number of Entities' indicates how many entities are contained in the transitional file. The remainder of the file contains specific information about each entity. The entity field structure consists of nine subfields: Entity Header, Entity Type, Entity Location, Entity Velocity, Entity Orientation, Munitions, Sensor, Jammer, and Task field. Each entity is uniquely identified by the number contained in the Entity Header field. The Entity ID should be unique in a scenario. The Force ID in the Entity Header structure indicates whether the entity is a friendly or enemy force.

If the entity has a name, the Entity Name field in the Entity Header stores it. The Entity Type Structure shows the kind of the entity. It follows the DIS standard as specified in the document, *Enumeration and Bit-encoded Values for use with IEEE 1278.1-1994, Distributed Interactive Simulation - Application Protocols* [IST94-1]. I designed for

Table 3.2 Data Structure of Transitional File

program extensibility by saving in DIS format, and a new entity type can be added by

referencing the DIS Enumeration Document. The Entity Location Structure shows the initial

3 - 17

position of the entity. For global use of the TP, this position must be converted to a global position. It is also designed for program extensibility using the coordinates system which DIS uses. The Entity Velocity Structure indicates the initial speed of the entity in meter/sec. The Entity Orientation contains the entity's direction vector in 3D space. Entity Velocity and Entity Orientation also use the DIS format. The Number of Kind of Munitions field shows the munitions load of the entity. For example, an F-16 can carry six US Mavericks, two US Sidewinders, 15 US Mk82s, and 2,000 US M50s. In this case the Number of Kind of Munitions field is four. The Munitions Type also follows IST94-1. Some entities have sensors and/or jammers for radio communication. That information is contained in the Sensor, and Jammer fields, respectively. The Task field indicates how many tasks the entity will perform. There can exist numerous missions depending on the specific characteristics of each simulation. I adopted the task types which ModSAF simulation currently uses for an initial implementation. Interested readers can refer to Appendix C for more detail on each field. The Number of Entities in the transitional file is given by the 'Number of Entities' entry declared on the first line. In the case where the number of items is initially unknown, memory requirements are minimized through dynamic memory allocation.

3.4.5 Translation Tables

The next several figures and table represent the scenario file data from each scenario source and how this data is mapped into the TP. The left-hand side of the Table 3.3 shows the number of variables that are in common area between two scenario in each simulation; the right-hand side of the table shows how many variables are defined in the TP. Figure 3.13, 3.14, and 3.15 depict the mapping of the scenario data from ModSAF, EADSIM, or BATTLESIM, respectively, into the TP. These figures use the same notation as in [Gard93].

Table 3.3 Percentages for Common Variables between Two Scenario

Simulation to Simulation	Number of Common Variables	Number of Common Variables defined in TP	Percentage(%)
ModSAF to EADSIM	18	18	100
ModSAF to BATTLESIM	21	21	100
EADSIM to BATTLESIM	24	24	100

3.5 Summary

This chapter defines the requirements for converting one scenario file to another. These

requirements can be grouped into five main areas: first, defining a TP; second, loading a source

scenario of a source simulation; third, mapping the source scenario to the TP; fourth, remapping

the TP to a transitional target scenario prototype, and finally, saving it as a target scenario for a

target simulation. Specific implementation details of the goals are discussed in the next chapter.

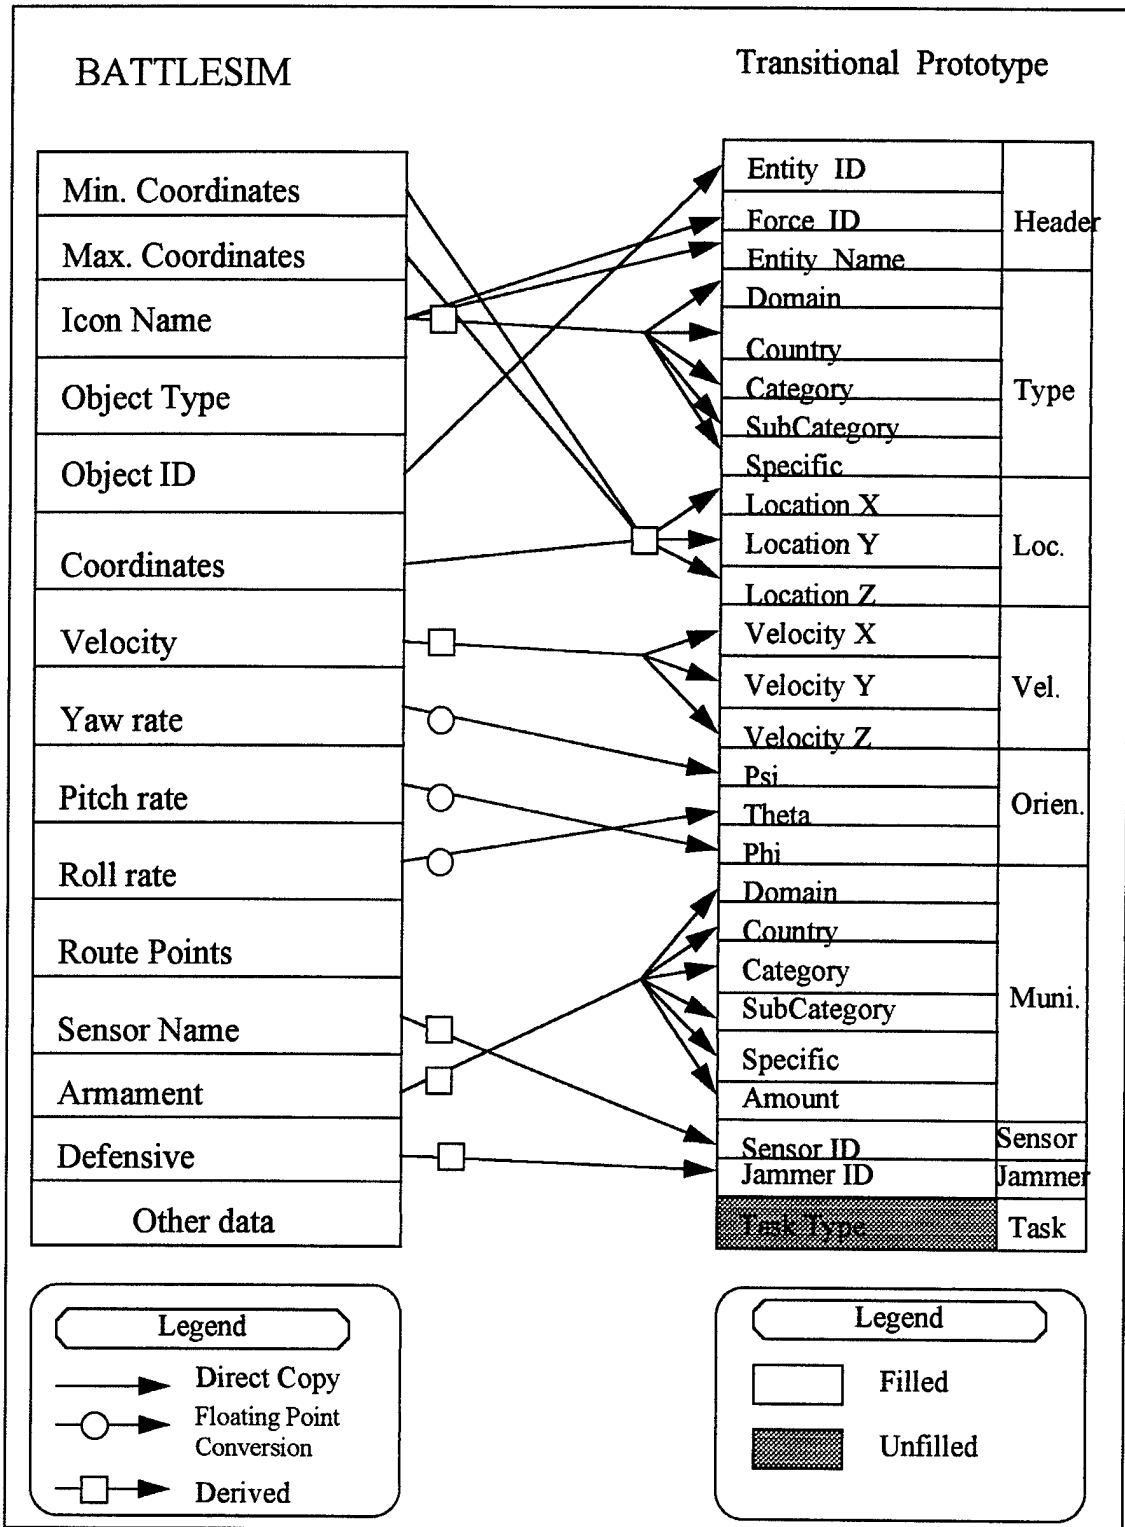

Figure 3.15 Transitional Prototype mapping for BATTLESIM scenario

IV. System Implementation

4.1 Introduction

This chapter discusses the implementation of the Scenario File Translator (SFT)'s design defined in Chapter 3. This implementation utilizes five subsystems: a loading system, a mapping system, a remapping system, a saving system, and a user interface system. The loading system reads a source scenario and stores it to a source scenario prototype. The mapping system transforms the transitional source scenario prototype to a Transitional Prototype (TP). The remapping system transforms the TP once more into a transitional target scenario prototype. The saving system writes the transitional target scenario prototype as a scenario file which can then be run by the target simulation. Finally, the user interface system provides a Graphics User Interface (GUI) to this program easier to run. All programs are written in the C programming language and were tested on SGI and Sun Workstations.

4.2 Loading a Scenario File

Reading a scenario file stores the scenario in computer memory. For this to work, a data structure which defines the organization of the scenario is needed. This structure is called the transitional source scenario prototype. Since the SFT operates three simulations' scenario types, this section discusses the loading system for each of the three scenarios.

4.2.1 Loading a ModSAF Scenario File
There are two ways to load a ModSAF scenario file. The first way is to use built-in libraries in the ModSAF program which do more than simply read the file and the other are to design and develop a new function to only read the scenario file. Each method has its own advantages and disadvantages.

First, using the ModSAF built-in libraries, we save time since we do not need to design and implement new functions; however, it is necessary to include many unnecessary files even

though a large number of unused functions may be contained in those files. This results in excessive compilation requirements. This method is inefficient, since the loading system of the SFT needs just one routine to read a scenario file. Conversely, designing and implementing a new function is attractive, because it simplifies the general organization of the program. On the other hand, this method requires additional work for designing a scenario data structure to implement the loading system. Since program readability and understandability are more important, I chose to design and implement a new library.

As mentioned in Section 2.4.1.2, the structure of a ModSAF scenario file consists of two parts: the Header part and the Entity part. The Header part describes the scenario organization, and the Entity part describes the entities in the file. The Entity part is also divided into the File Entry part and the Class part. The File Entry part has basic values for scenario class, and the Class part describes all about the class. The most important information in the Header part is the number of entities in the scenario file. The ModSAF loading system reads classes individually. The number of classes read is given by the number of entities. In the File Entry part, the object type and the variant size of the class is also important. Moreover, it is necessary to combine the classes with their related entities. Once the scenario file has been read, it is stored in the transitional prototype data structure for ModSAF scenarios. The minimum memory requirement to read a ModSAF scenario file with varying number of entities is described in Table 4.1. Examples shown are for cases where each entity has just one task.

4.2.2 Loading an EADSIM Scenario File Because EADSIM scenarios are saved in a text format, it is relatively easy to understand their organization and to develop an internal data structure for EADSIM scenario file information.

Two primary files are needed to build an EADSIM scenario: the scenario file and the laydown file. The laydown file stores all the information about the entities which compose a scenario, and the scenario file describes initial setup conditions and references the related laydown

Table 4.1 Required Memory Size for Loading a ModSAF Scenario File

(* B : Bytes)

| Entity Number | Header Part | Number of Class | Entity Part | | Total (KBytes) |
			File Entry Part	Class Part	
1	72 B	30	360 B	3,764 B	4.1
100	72 B	3,000	36,000 B	376,400 B	405.7
1,000	72 B	30,000	360,000 B	3,764,000 B	4056.7
10,000	72 B	300,000	3,600,000 B	37,640,000 B	40,556.4

file names. Additional files are required to organize a scenario; however, these two former files are more important than the others.

To load an EADSIM scenario, you must know which laydown files are connected to a scenario. The laydown files are read in order to get the entity information composing the scenario. Once this data is stored in the transitional EADSIM source prototype as defined in Chapter 3, then it is possible to progress to the next phase, the mapping phase. This stage is discussed in the Section 4.3.

Loading an EADSIM scenario is straightforward; just read the text files into the transitional EADSIM source prototype data structure. In the case of a scenario file, only the laydown file names in this file are important since the remainder of its data is only used for building the EADSIM scenario itself. However, the loading system reads all the data in an EADSIM scenario file for further use since currently unused data may be useful later.

In the case of EADSIM, the required memory size of a typical scenario file including laydown file names, with one entity is about 8.3 Kbytes. As with ModSAF, EADSIM scenario file size is dependent on the number of entities. Table 4.2 shows typical cases for scenarios with varying number of entities.

Table 4.2 Required Memory Size for Loading an EADSIM Scenario File

(* B : Bytes)

Entity Number	Scenario File	Laydown File	Total (KBytes)
1	7,509 B	988 B	8.3
100	7,509 B	98,000 B	103.8
1,000	7,509 B	988,000 B	972.2
10,000	7,509 B	9,880,000 B	9,655.7

4.2.3 Loading a BATTLESIM Scenario File   It is also fairly straightforward to load a

BATTLESIM scenario file, since it is also saved as a text file like an EADSIM scenario file. To

load a BATTLESIM scenario file, the data is extracted from each line in the source file into the

transitional BATTLESIM source prototype. When reading a data line from the source scenario

file, if the first character of the line is an asterisk defined by the programmer, it skips the line and

reads the next line automatically so that some comments can be written in the scenario file for

providing better understanding. Figure 4.1 shows this algorithm.

```
char          Data_Line[MAX_LINE_LENGTH];
while (!feof(File_Ptr))              /* read until end of file */
{
  fgets (Data_Line, MAX_LINE_LENGTH, File_Ptr);
  switch (Data_Line[0])
  {
    case '*':                  /* ignore all lines that starts with characters */
    case '\n':                 /* '*', '\n', '\0', or space                    */
    case '\0':
    case ' ':
      break;
    default:
      return Good_Line;   /* Boolean value */
  }                         /* end of switch */
}                           /* end of while */
```

Figure 4.1 Algorithm for Reading a BATTLESIM Scenario file

Assuming an entity has only one route point, sensor, armament, target, and defensive system in a BATTLESIM scenario, then 276 Bytes are needed for a scenario with one entity. Table 4.3 describes these memory requirements for similar scenarios with different numbers of entities..

Table 4.3 Required Memory Size for Loading a BATTLESIM Scenario File

Entity Number	Header Part	Entity Part	Total (KBytes)
1	144 B	132 B	0.27
100	144 B	13,200 B	13.0
1,000	144 B	132,000 B	129.1
10,000	144 B	1,320,000 B	1,289.2

4.2.4 Loading a Transitional File   As will be seen in Section 4.5.4, a Transitional File is also saved in text format so it can be easily verified when viewing the components in it. A Transitional File is read and loaded into the Transitional Prototype data structure using the same algorithm for loading a BATTLESIM scenario file.

The required memory size for each entity in the TP depends on the entity's number of tasks. If an entity has an 'Assault' task (the largest task with respect to memory requirements), the entity needs 271 Bytes. This is shown in Table 4.4 with other examples.

Table 4.4 Required Memory Size for Loading Transitional File
(* B : Bytes)

Entity Number	Without Task	Task	Total (KBytes)
1	218 B	53 B	0.26
100	21,800 B	5,300 B	26.4
1,000	218,000 B	53,000 B	264.6
10,000	2,180,000 B	530,000 B	2,646.4

4.3 Mapping a Scenario Prototype to a Transitional Prototype

Mapping to a Transitional Prototype (TP) is necessary to convert a source scenario to a target scenario. The more source types we map to the TP, the more data we remap to target scenario prototype and the more we increase the conversion percentage. This results in a more well-translated target scenario. Because the SFT uses scenarios from three simulations, six mapping routines are needed. This is because each simulation needs two mapping routines: one to the TP from the transitional source scenario prototype, and another from the transitional target scenario prototype to the TP. This section discusses mapping a transitional source scenario prototype to the TP. Section 4.4 discusses remapping the TP to a transitional target scenario prototype.

4.3.1 Mapping a ModSAF Prototype to a Transitional Prototype

A ModSAF scenario file is stored internally as a transitional ModSAF prototype as defined in Section 3. Mapping from this structure to the TP is done by traversing the stored structure. Ten of the 21 ModSAF classes are essential for mapping to the TP. They are the Overlay Class, the Point Class, the Line Class, the Sector Class, the Unit Class, the Task Class, the Task State Class, the Task Frame Class, the Task Authorization Class, and the Minefield Class. Among them, four classes are more useful for mapping to the TP (see Figure 3.13). To begin, it is necessary to determine how many entities there are in a scenario file. The number of the entities is same as the Unit Class number in the ModSAF scenario file. If the number of the entities in a scenario file is 50, then the Unit Class number is also 50. Thus, if Unit Class number is determined while traversing the transitional ModSAF prototype, the number of the entities in the TP is found easily. Since the Unit Class has direct information of Entity ID, Force ID, and Entity Name in the TP, every time a Unit Class is detected they are mapped to the TP using these items. The TP Entity Type is stored in the DIS format which has Domain, Country, Category, SubCategory, and Specific values. The variable 'objectType' in a Unit Class is related to the DIS format by a ModSAF function which converts this variable to the DIS format.

Since ModSAF entity location uses the topocentric coordinate system in which the origin of the coordinates is given point, we cannot directly use these coordinates within the TP. It is necessary to match this location to the DIS geocentric coordinates. The origin of the geocentric coordinate system in DIS is the centroid of the earth as shown at Figure 4.2 [IST94]. ModSAF also provides a function to support this conversion.
Figure 4.2 Geocentric Cartesian Coordinates in DIS

Since ModSAF must map Entity Velocity and Entity Orientation to DIS formats when it sends DIS PDUs, we can also use functions to build the TP. The kind of munitions in an entity is known from a 'munition' variable in a Unit Class of ModSAF scenario file. Another ModSAF function converts this object type to a DIS format is also used here. The amount of munition that the entity has is also stored in the 'munition' variable in a Unit Class. The Task Type in the TP can be determined after integrating several classes in the ModSAF scenario file. Some classes

which help to determine the TP Task Type are the Task Class, the Task State Class, the Task Frame Class, and the Task Authorization Class. ModSAF 2.1 defines 33 tasks, and the SFT accommodates all of them to provide a complete task mapping. Appendix B shows the task types defined within the TP.

4.3.2 Mapping an EADSIM Prototype to a Transitional Prototype Of the two data structures in the EADSIM prototype, i.e., one for the scenario file and the other for a laydown file, only the data structure corresponding to the laydown file can be directly mapped into the TP since the data in the scenario file is EADSIM specific except for the laydown file names. Specifically, five data items from the laydown data structure cover almost every part of the TP. The Entity ID and the Entity Task in the TP Entity Header are not known directly from the laydown file, so the most widely used default values are put into them. The Entity ID is produced sequentially whenever an Entity is detected, and when the entity is an aircraft the Entity Task is either 'Assault Ground Target' or 'CAS Mission' since it is required to attack all enemy forces on its path (See Figure 3.14).

We determine the Force ID in the Entity Header part, whether it is friendly or an enemy force, after checking the System ID in an EADSIM scenario file. The TP Entity Name is known when referring to the EADSIM Military ID. The TP Entity Type is saved as an enumeration type in DIS format using the EADSIM System ID. Although, there is no item in the EADSIM prototype which indicates an entity's initial location, the starting location can be determined as the first point in the path the entity passes through. This point must also be changed to a DIS geocentric coordinate system value.

We derive the TP Entity Orientation by computing the difference between the first and the second entity positions in its path. This difference is converted to the DIS format, and stored to the Entity Orientation in the TP. An entity's munition load is determined by referencing another

file in EADSIM using the System ID of the entity. This data must be converted into the DIS format. The Sensor Name and the Jammer Name are determined from the platform of the entity directly.

4.3.3 BATTLESIM Prototype to Transitional Prototype The BATTLESIM prototype consists of the Header part and the Entity part as described at Section 2.4.3.2. The items in the Header part to match to the TP include the icon definition records as well as the minimum and maximum coordinates of a terrain database. Minimum/maximum coordinates are needed when converting the entity position to geocentric coordinate system in DIS, and Icon Definition Records are for the type of the entity. The datum that is not mapped directly to the TP from a BATTLESIM prototype is the Task Type. We use the most widely accepted default values here. In case of an aircraft, we set the Task Type to either 'Assault Ground Target' or 'CAS Mission.' The task 'Assault' or 'Move Task' is used for a ground entity.

We derive the TP Entity ID from the BATTLESIM object ID. Icon Name determines the Force ID, Entity Name, and Entity Type of the TP. Entity with US icon name is recognized as friendly; Soviet icon name characterizes entity as an enemy. Otherwise, the entity is regarded as 'others.' The TP Entity Type is also determined by the icon name and translated into the DIS format. Table 4.5 gives some examples for mapping the BATTLESIM icon name to a DIS Entity name.

Table 4.5 Icon Name in BATTLESIM vs. Entity Name in DIS

Icon Name in BATTLESIM	Entity Name in DIS
f18	FA18
mig	USSR_Mig21
missile	US_CG41
tank	US_M1A1
truck	US_M35A2

The TP Entity Location is calculated using the coordinates of the entity and the minimum/maximum coordinates of the terrain file in the BATTLESIM scenario file. The TP Entity Velocity and the TP Entity Orientation are described in the BATTLESIM scenario file; however they must be converted into the DIS format. The munition type of an Entity is related to the BATTLESIM armament type; however, it cannot be used directly in the TP, but is converted to DIS format. The entity's Sensor ID and the Jammer ID are related to the Sensor Name and Defensive system in BATTLESIM.

4.4 Remapping a Transitional Prototype to a Transitional Target Scenario Prototype
In the process of converting a TP to a target scenario prototype, some items which are not represented by the target scenario are lost. In addition, it is also often necessary to generate unspecified parameters as default values in a target scenario prototype.

4.4.1 Transitional Prototype to ModSAF Scenario Prototype To make a file which ModSAF can read after remapping from a TP, it could be accomplished by a function fitting the data structure of ModSAF scenario file. I think the best approach to create the ModSAF target file is to use a routine which ModSAF provides. It is necessary to map into a Persistent Object (PO) database for saving as a scenario of ModSAF. Since much information about Semi-Autonomous Forces (SAF) behavior cannot be shared via the DIS protocol, the PO protocol was created to provide a more flexible and scaleable interface between the components of the SAF system. The PO protocol enables the sharing of behavioral states, command and control information, and system administration. ModSAF software modules have unlimited access to all the information being broadcast via this protocol, provided they are running on the same PO 'database ID.' The database ID is an identifier in the PO PDU Header that identifies with which repository of persistent objects or 'database' the application interacts.

ModSAF program provides a function 'po_create_object()' which creates an entity in the PO database. We use the function to build of each ModSAF class. Ten of 21 (see section 4.3.1) ModSAF classes are involved when remapping to a ModSAF scenario file. Among these, the Unit Class has the most important role. This class stores the general data of an entity. The matching items from the TP are 'overlayID,' 'forceID,' 'objectType,' 'marking,' 'location,' 'direction,' 'speed,' and 'munition' of the Unit Class (see Figure 4.3). The ModSAF overlayID is mapped from the TP Entity ID, and the ModSAF objectType is converted from the data that is saved in DIS format to an integer type variable through a ModSAF utility function.

The marking in the Unit Class is copied from the TP entity name. Getting the ModSAF location value requires a routine to convert the DIS format data in the TP into ModSAF terrain database. Direction, speed, and munition in the Unit Class are passed in the same way as ModSAF location data. Translating the TP task into each ModSAF Task class is required to map related data using the TP Task Type module. After accomplishing this, we build the PO_database.

4.4.2 Transitional Prototype to EADSIM Scenario Prototype In section 2.4.2.2, we mentioned that EADSIM uses two files to build a scenario. Here we describe the process of mapping from each TP entity to the EADSIM scenario prototype. The laydown file name is contained in the scenario data structure. This file contains the platform data of each EADSIM entity.

The EADSIM program allows several laydown files in a single scenario; however, the SFT uses only one laydown file to save all entities in the TP. Since this file has all the information of a scenario, we only need to open this one file when we want to see what entities are in the scenario. The EADSIM Military ID of an entity is same as the TP Entity Name. The EADSIM System ID can be obtained using the TP Entity Type. The Sensor Name and the Jammer Name in the EADSIM prototype are also derived from the TP. The TP did not provide EADSIM Way Point directly; however, we can derive the data from the TP task type. If an entity

has a task, a route which the entity should follow is stored in the TP. The Way Point can be built using these route data.

4.4.3 Transitional Prototype to BATTLESIM Scenario Prototype A BATTLESIM scenario prototype contains a Header Part and an Entity Part. The data needed to map to the Header Part is the Icon Definition part. For determining these icon definition records, it is necessary to describe the Header Part after extracting the kinds of entities which are stored in Entity Part. The BATTLESIM entity object type determines the icon number which matches with the TP Entity Type. The TP Entity ID determines the BATTLESIM object ID. The BATTLESIM coordinates are found using both the TP location and minimum/maximum coordinates as described in the Header Part.

The BATTLESIM Velocity and Orientation are derived from the TP velocity and the orientation. The sensor name and the defensive system are recognized by the Sensor ID and the Jammer ID, respectively. Finally, the armament of an entity can be derived from the TP's munition type.

The next three figures represent the transitional prototype how its data is mapped into each target scenario prototype. The size of each box is not intended to represent the actual file size.

Figure 4.5 Remapping to a Transitional BATTLESIM Prototype

4 - 15

4.5 Saving a Transitional Prototype as a Target Scenario

The last phase of translating a source scenario to a target scenario is to write the remapped target prototype as a target scenario that a target simulation can read.

4.5.1 Saving as a ModSAF Scenario

Since a PO_database is created in the process of mapping into the transitional ModSAF prototype, the task of saving the PO_database into an actual file is very simple. We use a function provided by the ModSAF program. When using the function, all the data in PO_database are stored into a user defined file name.

4.5.2 Saving as an EADSIM Scenario

The first thing to do is to save a scenario file which an EADSIM can read from transitional EADSIM prototype. At this time, there is nothing to get from the transitional EADSIM prototype. Only the laydown file name is designated by user input and all information of a scenario is stored here. Several different file paths are stored in the EADSIM scenario file, and the directory path that is running the EADSIM is also needed. Because typing in the directory path whenever the Scenario File Translator is running is inefficient, we store the EADSIM running directory path in a files. This makes the SFT run more efficiently. The laydown file that stores the information of an entity is written to a text file fitting the transitional EADSIM prototype. The transitional EADSIM Laydown prototype can be saved in a straightforward manner since it is designed the same as the data structure of the laydown file.

4.5.3 Saving as a BATTLESIM Scenario

To save a transitional BATTLESIM prototype data structure, we simply write the items in the structure to disk sequentially. Because there is no way to determine the terrain filename or the data about BATTLESIM section, thus, the user must provide the values when the file is saved.

4.5.4 Saving as a Transitional File

Sometimes it is necessary to save the Transitional Prototype itself for further uses after mapping the source scenario to the TP. This is also efficient when testing a scenario in several other simulations since the SFT just needs to read a source scenario one time. Once the SFT reads a source scenario converts it, and saves it as a TP,

there is no need to re-read and remap the scenario for testing with other simulations. Just reading the Transitional File is enough to convert the source scenario to a target scenario. Saving as a Transitional File means to write the items that have been mapped to the TP in the format of Transitional Prototype. The SFT saves the TP to a text format. The user can easily understand the data since the SFT also writes some comments in the file.

4.6 User Interface

This section presents the result of the SFT user interface. The SFT provides two interfaces; GUI and Command Line Interface (CLI). Basically the CLI is provided to every machine even in the places where the GUI is also available.

4.6.1 Graphics User Interface (GUI)
Figure 4.6 is a picture of the SFT main window. The row of menus at the top of the window (New, Run, Quit, and Help) allows immediate access to several functions. A selection of the 'New' button initializes the SFT. The 'Run' button causes the SFT to translate a source scenario to a user-defined target scenario according to the current settings. If a necessary value is omitted, the SFT displays an error message. The 'Quit' button terminates the program, and the 'Help' button displays program-specific information to the user.

The rest of the main window is called a scenario selection area. It is divided into two areas: the source scenario area and the target scenario area. Both sides have same purpose, namely, to select a scenario type and a scenario file name.

Figure 4.6 The Main Window of the SFT

The scenario selection area allows the user to choose the source/target simulation. The user can type a directory path and a file name in the 'FileName' display area or can use 'File Browse' button to search the directory structure for a file name. Error messages, warning messages, or processing messages are displayed in one of several different types of windows.

4.6.2 Command Line Interface   A command line interface is also supported by the SFT for when the Motif library is not available. To use this interface, the user types the kind of a source/target simulation and the name of a source/target scenario file. The SFT then builds the target scenario file which the user defined. This interface has a validating function so it filters errant inputs. Appendix C shows the usage of SFT Command Line Interface.

4.7 Summary

This chapter described how the Scenario File Translator system is implemented. The SFT has five subsystems: the loading system, the mapping system, the remapping system, the saving system, and the user interface system. Actual data structures and methods for implementing the program followed the design specification. The next chapter presents the results of this system and offers suggestions for future work.

V. Results

5.1 Introduction

This chapter discusses the approach taken to ensure that the system, as implemented, fulfills the original requirements. Several cases are tested and the results are illustrated using a series of pictures taken within the SFT. This chapter also describes my observations of the test results.

5.2 The Scenario File Translator Test Cases

There are nine different test cases represented in the SFT. They are referred to as Test 1 through Test 9. Each test case represents a different type of conversion. This section shows what a source scenario looks like in a source simulation and not its translated scenario as represented in the target simulation.

5.2.1 Test 1 : ModSAF to EADSIM
Figure 5.1 is a picture of a ModSAF simulation produced by ModSAF itself. It has 18 entities, and each entity has a different task. This scenario is used for Test 1, Test 2, and Test 3. Figure 5.2 shows the ModSAF scenario after EADSIM scenario and executed by EADSIM. It also has 18 entities which is the same as the number of entities in the ModSAF. Additionally, every entity location is the same as the one in the ModSAF, and every task for the ModSAF entities is also properly converted to the EADSIM scenario.

5.2.2 Test 2 : ModSAF to BATTLESIM
Since the ModSAF scenario is already converted to the Translated File in the Test 1, there is no need to read the ModSAF scenario again. After converting the Transitional File to the BATTLESIM format, it also has 18 entities.

Once again, everything in the ModSAF scenario was properly translated to the BATTLESIM scenario.

5.2.3 Test 3 : ModSAF to ModSAF   It is interesting to "convert" the ModSAF scenario to a ModSAF scenario after mapping it to the Transitional File, since the comparison between two scenarios demonstrates the fidelity of the conversion, showing clearly what is and is not mapped. Figure 5.3 shows a translated scenario from a ModSAF source scenario to a ModSAF target scenario. Notice, there are no changes between Figure 5.1 and Figure 5.3. The basic elements of the scenario are well translated with lost data during the mapping process restored by proper default values.

5.2.4 Test 4 : EADSIM to ModSAF   Figure 5.4 is a snapshot of an EADSIM scenario. It has 10 entities, and each entity has a different flight path and mission. This particular EADSIM scenario is used for Test 4, Test 5, and Test 6. Figure 5.5 is a picture of a ModSAF simulation executing a converted scenario from the EADSIM by the SFT. Some entities which are not represented in ModSAF (such as an EADSIM 'Air Base') are translated into the 'unknown' entity.

5.2.5 Test 5 : EADSIM to BATTLESIM   The number of entities in the BATTLESIM is the same as the number of entities in the EADSIM even after converting the scenario. Each BATTLESIM entity has the same route with an EADSIM entity route to perform the mission in the EADSIM source scenario.

5.2.6 Test 6 : EADSIM to EADSIM   I also tested converting an EADSIM scenario to an EADSIM scenario through the Transitional File. Figure 5.6 shows the playback of the target scenario after its conversion by the SFT. There are no changes between Figure 5.4 and Figure 5.6 similar to that of Test 3, ModSAF to ModSAF. The result scenario file has just one laydown file. It successfully combined several laydown files into one laydown file.

5.2.7 Test 7 : BATTLESIM to ModSAF   Figure 5.7 depicts ModSAF scenario as it executes the scenario after being converted from BATTLESIM by the SFT. BATTLESIM source scenario has 9 entities, and each entity has a different path. ModSAF shows each entity has its origin path and proper mission fitting the ModSAF task.

5.2.8 Test 8 : BATTLESIM to EADSIM   Figure 5.8 shows a snapshot of a simulation run by EADSIM. There is the same number of entities in the BATTLESIM, and every entity location in the BATTLESIM is well translated into an EADSIM location. The entity path in BATTLESIM is also transferred into EADSIM, so every entity which has a path goes through with the translated path.

5.2.9 Test 9 : BATTLESIM to BATTLESIM   I compared file format and file size after translating the original BATTLESIM scenario to the translated BATTLESIM scenario. Actually there are no differences between them. So, translating BATTLESIM scenario into another scenario has successfully worked.

5.4 Observation

We tested each possible case with our three simulations. The tests are demanding, because in each case the source scenario I produced most of its special purpose features. Thus, I could also test the interoperability between heterogeneous simulations.

According to these tests, we can make the following observations:

- Every entity type in a source scenario was completely translated into a target scenario.

- Every location in a source scenario is converted as the same position in a target scenario.

- The task definition in the TP covered every scenario's task type.

- The choice to use the DIS format data for Transitional Prototype (TP) such as entity type, entity location, entity velocity, entity orientation and entity munition type was a good decision.

- It was shown that using the intermediate format to correct a source scenario to a target scenario is a better method than a direct mapping. Assume there are currently N simulations. In case of a direct mapping method, $N*(N-1) = N^2 - N$ routines are needed; however, only $2*N$ routines are needed with using an intermediate format.

Based on these observations, the general objectives which are defined in Chapter Three are accomplished.

5.5 Summary

This chapter discussed the top-level of the SFT organization, and the test results. It also provided the observation of these test cases for converting a scenario to a target scenario. The next chapter formulates some conclusions and provides some recommendations for future work.

VI. Thesis Summary

6.1 Introduction

The effectiveness of computer simulation in the military is especially apparent, since real combat conditions are often costly to create for testing some scenarios. There now exists a variety of scenario generation and analysis products which have differing purposes and functions. Due to the particular purpose of each simulation, we cannot use one scenario of a simulation directly with another simulation without a translator since there is no standard scenario format. Interoperability between simulations is becoming more important in large scale simulation and distributed exercises. Translating scenarios to support interoperability is a useful process. I chose to remap to a target simulation after mapping into an intermediate prototype. This is more efficient because it is not dependent on the number of existing simulations. I proposed the transitional prototype as an intermediate format, and also developed the software tool (Scenario File Translator) that aids in the translation of scenario file formats with this transitional prototype so that scenarios developed by different simulations can be run by each other. After some test cases with the SFT, this scenario translating work has been achieved.

6.2 Recommendations for Future Work

There are several approaches for follow-on work in the SFT. One of the biggest areas of concern in the system is how the definition of the Transitional Prototype (TP) can be made more general. The prototype that covers all of the information of all simulation is the ideal format for this work. Table 6.1 is a snapshot of the work proposed in this chapter. Each of the primary system components – transitional prototype, DIS PDU, compatibility, and machine independence – is a candidate for future work.

6.2.1 Transitional Prototype As mentioned in Section 3.4.3, a set of information which covers all data for all simulations is the ideal format for the TP. However, this is not practical, and therefore we might focus on improving the data structures and the data formats in the TP as the best way to cover every simulations' scenario. As the TP data structure is generalized it will provide program for greater reusability and extensibility. A more detailed definition of the task type allows the target scenario to inherit the special purpose of a source scenario. We can also enhance the mapping process for more accurate translation. Since the more we map to the TP the more we extend the common area between simulations, even a small piece of data is important. Since the most widely-used default values are used when there is no represented data to a target scenario for mapping, finding a correct value for those data is another important process to increase the conversion percentage between two simulations.

6.2.2 DIS PDU Since most distributed simulations support DIS, grabbing the PDU from the network and building a state of the battlefield provides another advantage. Even if the mapping procedure of a simulation is not built, we can extract the current state of a scenario and can save it as the Transitional File which can be used by another simulation. The best PDU to determine the current state of a scenario is the 'Entity State PDU' (see Table 2.1). The PDU has information of each entity such as entity type, velocity, and location. Using the PDU we can rebuild a scenario which contains all the simulations on the network. Of course, we can select some specific PDUs by 'Exercise ID' in PDU Header. However, since DIS PDUs send current events over the network, it is not possible to determine the task of an

Table 6.1 Proposed Future Work

Functional Area	Proposed Work
Transitional Prototype	Improving data structure and data format
	Extend the type of task
	Enhance accuracy of mapping process
	Correct inserting for default values
DIS PDU	Develop DIS "Entity State PDU" snapshot function
	Select specific PDU with Exercise ID in PDU Header
	Changing TP to DIS PDU
	Send converted DIS PDU from TP via network
	Receive other DIS PDUs relating the TP
Machine Independence	Provide 'Makefile' to compile on any machine
	Analyze the computer system to allocate optimized memory size
	Enhance stability and extensibility
Compatibility	Accommodate other prototype
	Transfigure to other format
	Accompany with DIS PDU

entity as described in Section 3.2.1.1. As DIS PDU is more well developed we can alleviate this problem. Conversely, we can build a procedure which changes a TP to PDUs because the TP already uses the DIS format. That is another benefit since we can send the TP via the network through the DIS PDU, providing for program extensibility.

6.2.3 Machine Independence It is desirable for the SFT to run on any machine to support many currently-existing simulations. Of course, there is a way to translate a scenario on one type of machine to a target scenario on another type of machine. When the scenarios are transferred to the machine which has the SFT, a target scenario can be made and can be sent to the machine which uses the target scenario. However, it depends on the network state. For more stable support, it is necessary to compile on any machine. The flexible and comprehensive 'Makefile' supports this.

6.2.4 Compatibility I chose DIS format to save some scenario data such as entity type, entity location, and munition type. If a more well-defined format to send a current state of a scenario is developed, or if there is another format to describe data of scenarios, compatibility with these formats extends the usability of the SFT.

6.2.5 Memory Size In the current program, all data of the source/target scenario and TP are stored in computer memory. The required memory size is described in Section 4.2. The potential problem is an out-of-memory exception. Memory size is not a big problem in this area since we can increase computer memory relatively inexpensively. However, we need to consider the possibility that the memory is not sufficient to store the whole data of a scenario which has a hundred thousand entities, or a million entities, or a billion entities in extreme cases. Of course, there are several techniques to solve this problem. The more we minimize the required memory size, the more the SFT is stable. One of the ways to minimize the required memory size is to optimize the TP data structure. When we determine the best size of each variable, we can reduce the TP memory size. When the memory is not enough even after optimizing the data structure, another way is to use a hard disk drive to temporarily save current state of the TP.

6.3 Conclusion

This thesis effort produces a system which translates scenarios of one format to scenarios of a different format in order to increase interoperability between simulations. Although this thesis effort concentrated on three specific simulations ModSAF, EADSIM and BATTLESIM, this work can also be applied to other simulations, and that task is simplified by the TP.

Appendix B. Enumeration Type for Task Type of Transitional Prototype

B.1 Task Name

Field Value 1-99 : Ground Mission

Field Value 100-149 : Air Mission

      100-124 : FWA Mission

      125 - 149 : RWA Mission

Field Value 150-199 : Surface Mission

Field Value 200-249 : Space Mission

Field Value 250-255 : Extra

Table B.1 Enumeration Type of Task Name

Field Value	Task Kind
0	Others
1	Move
2	Road March
3	Follow a Vehicle
4	Follow Simulator
5	Pursue
6	Hasty Occupy Position
7	Assault
8	Traveling Overwatch
9	Overwatch Movement
10	Withdraw
11	Breach
12	Attack By Fire
13	Concealment
14	Delay
15	Repair
16	Sevice Station
17	Cross-leveling
18	Change Formation
19	Rendezvous
100	FWA Sweep
101	FWA CAP
102	FWA CAS Mission
103	FWA Ingress
104	FWA Attack Ground Target

105	FWA Egress
106	FWA Return to Base
107	FWA Interdiction Mission
125	RWA Fly Route
126	RWA Hover
127	RWA Orbit
128	RWA Assemble
129	RWA Attack
130	RWA Hasty Occupy Position

B.2 Data Structures for Each Task Type

B.2.1 Move

Table B.2 Task 'Move' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
unsigned char	TravelType	Enumeration Type
unsigned char	Formation	Enumeration Type
float	RateOfMarch	
float	CatchUpSpeed	
float	DismountedSpeed	
unsigned int	FollowingLeader	
unsigned int	FollowingLeaderDegree	
float	FollowingLeaderDistance	
unsigned char	NumPoints	LeftBoundary
tf_point *	PointAddr	
unsigned char	NumPoints	RightBoundary
tf_point *	PointAddr	
unsigned char	Spacing	Enumeration Type
float	UserSpecifiedSpacing	
float	IFVOffsetX	
float	IFVOffsetY	

B.2.2 Road March

same as Task "Move".

B.2.3 Follow a Vehicle

same as Task "Move".

B.2.4 Follow Simulator

Table B.3 Task 'Follow Simulator' data structure

Type	Variable Name	Remark
unsigned char	SimulatorToFollow	
unsigned char	TravelType	Enumeration Type
unsigned char	Formation	Enumeration Type
unsigned char	Spacing	Enumeration Type
float	UserSpecifiedSpacing	
float	RejoinSimDistance	

B.2.5 Pursue

same as Task "Move".

B.2.6 Hasty Occupy Position

Table B.4 Task 'Hasty Occupy Position' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	BattlePosition
tf_point *	PointAddr	
unsigned char	NumPoints	EngagementArea
tf_point *	PointAddr	
tf_location *	LeftTRP	
tf_location *	RightTRP	
float	Speed	
tf_location *	TriggerLine	
unsigned char	TriggerCriteria	
unsigned char	TriggerUnitSize	
unsigned char	NumPoints	SecondaryBattlePosition
tf_point *	PointAddr	
unsigned char	NumPoints	SecondaryEnggArea
tf_point *	PointAddr	
tf_location *	SecondaryLeftTRP	
tf_location *	SecondaryRightTRP	

B.2.7 Assault

Table B.5 Task 'Assault' data structure

Type	Variable Name	Remark
unsigned char	NumObjectives	Objectives
tf_point *	ObjectivesAddr	
unsigned char	NumPoints	Route
tf_point *	PointAddr	
float	Speed	
float	DismountedSpeed	
float	StoppingAssaultCriteria	
unsigned char	SecureObjective	Enumeration Type
unsigned char	Formation	Enumeration Type
unsigned char	Spacing	Enumeration Type
float	UserSpecifiedSpacing	
float	IFVOffsetX	
float	IFVOffsetY	

B.2.8 Traveling Overwatch

Table B.6 Task 'Traveling Overwatch' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
float	RateOfMarch	
float	CatchUpSpeed	
float	SupportGroupFollowingDistance	
unsigned char	Formation	Enumeration Type
unsigned char	Spacing	Enumeration Type
float	UserSpecifiedSpacing	
unsigned char	ConformToTerrain	boolean

B.2.9 Overwatch Movement

Table B.7 Task 'Overwatch Movement' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
unsigned char	UseConcealedRoute	boolean
unsigned char	NumPoints	LeftBoundary
tf_point *	PointAddr	
unsigned char	NumPoints	RightBoundary
tf_point *	PointAddr	
unsigned char	Movement	Enumeration Type
float	RateOfMarch	

float	CatchUpSpeed	
float	DismountedSpeed	
unsigned int	FollowingLeader	
unsigned int	FollowingLeaderDegree	
float	FollowingLeaderDistance	
unsigned char	Spacing	Enumeration Type
float	UserSpecifiedSpacing	
unsigned char	Formation	Enumeration Type
unsigned char	DIFormation	
float	IFVOffsetX	
float	IFVOffsetY	

B.2.10 Withdraw

Table B.8 Task 'Withdraw' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
unsigned char	Smoke	Enumeration Type
float	Speed	
float	SpeedLimit	

B.2.11 Breach

Table B.9 Task 'Breach' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
unsigned char	CreateMarkers	boolean
float	MaxDistBtwMarks	
float	BreachLaneWidth	

B.2.12 Attack By Fire

same as Task "Hasty Occupy Position".

B.2.13 Concealment

Table B.10 Task 'Concealment' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
float	Distance	
float	RateOfMarch	
float	FrontWidth	
unsigned int	ForwardSpread	
unsigned int	BackwardSpread	

B.2.14 Delay

Table B.11 Task 'Delay' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	BattlePosition1
tf_point *	PointAddr	
unsigned char	NumPoints	BattlePosition2
tf_point *	PointAddr	
unsigned char	NumPoints	BattlePosition3
tf_point *	PointAddr	
unsigned char	NumPoints	BattlePosition4
tf_point *	PointAddr	
float	Speed	

B.2.15 Repair

Table B.12 Task 'Repair' data structure

Type	Variable Name	Remark
tf_location *	UMCPSite	
unsigned char	TowVehicle	
unsigned char	VehicleToRepair	

B.2.16 Sevice Station

Table B.13 Task 'Service Station' data structure

Type	Variable Name	Remark
unsigned char	SupplyUnit	

B.2.17 Cross-leveling

Table B.14 Task 'Cross Leveling' data structure

Type	Variable Name	Remark
tf_location *	CrossLevelingAreaLocation	
float	CrossLevelingAreaRadius	
unsigned char	SupplyToCrossLevel	Enumeration Type

B.2.18 Change Formation

Table B.15 Task 'Change Formation' data structure

Type	Variable Name	Remark
tf_location *	Destination	
unsigned char	Formation	Enumeration Type
unsigned int	FormationAngle	

B.2.19 Rendezvous

Table B.16 Task 'Rendezvous' data structure

Type	Variable Name	Remark
unsigned char	Partner	
tf_location *	Objective	
unsigned char	PUnitFormation	Enumeration Type
unsigned char	SUnitFormation	Enumeration Type
unsigned int	RelativePosition	
float	ParkingOffset	
float	MaxSpeed	

B.2.20 FWA Sweep

Table B.17 Task 'FWA Sweep' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
float	Speed	
float	Altitude	
unsigned char	RadarSearchMode	Enumeration Type
unsigned char	RadarVolumeAzimuth	Enumeration Type
unsigned char	RadarVolumeElevation	Enumeration Type
unsigned char	RadarVolumeRange	Enumeration Type

Type		
unsigned char	RadarVcSetting	Enumeration Type
unsigned char	RadarOrientationType	Enumeration Type
tf_location *	RadarOrientationLocation	
unsigned int	RadarOrientationAzimuth	
unsigned int	RadarOrientationElevation	

B.2.21 FWA CAP

Table B.18 Task 'FWA CAP' data structure

Type	Variable Name	Remark
tf_location *	CAPPosition	
unsigned int	CAPOrientation	
float	LenghOfLegs	
float	InboundLegSpeed	
float	OutboundLegSpeed	
float	CAPAltitude	
unsigned char	RadarSearchMode	Enumeration Type
unsigned char	RadarVolumeAzimuth	Enumeration Type
unsigned char	RadarVolumeElevation	Enumeration Type
unsigned char	RadarVolumeRange	Enumeration Type
unsigned char	RadarVcSetting	Enumeration Type
unsigned char	RadarOrientationType	Enumeration Type
tf_location *	RadarOrientationLocation	
unsigned int	RadarOrientationAzimuth	

B.2.22 FWA CAS Mission

Table B.19 Task 'FWA CAS Mission' data structure

Type	Variable Name	Remark
tf_location *	ForwardAirController	
unsigned char	NumPoints	RouteToForwardAirController
tf_point *	PointAddr	
unsigned char	NumPoints	OptionalReturnRoute
tf_point *	PointAddr	
float	FlightSpeed	
float	Altitude	
unsigned char	FlightMethod	Enumeration Type
unsigned char	Formation	Enumeration Type
unsigned int	TimeOnStation	
unsigned char	ActionsAfterMission	Enumeration Type

B.2.23 FWA Ingress

Table B.20 Task 'FWA Ingress' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
float	Speed	
float	Altitude	
unsigned char	Formation	Enumeration Type
unsigned char	MovementType	Enumeration Type
unsigned char	AtEndOfRoute	Enumeration Type

B.2.24 FWA Attack Ground Target

Table B.21 Task 'FWA Attack Ground Target' data structure

Type	Variable Name	Remark
unsigned char	NumTargets	
tf_point *	TargetAddr	
unsigned char	NumPoints	Route
tf_point *	PointAddr	
float	Speed	
float	Altitude	
unsigned char	MovementType	Enumeration Type
unsigned char	Formation	Enumeration Type
unsigned char	AttackGeometry	Enumeration Type
unsigned char	AttackEntry	Enumeration Type
unsigned char	AttackDelivery	Enumeration Type
weaponsenabled *	WeaponEnabledAddr	structure pointer
unsigned char	MissionType	Enumeration Type

Table B.22 Task 'weaponsenabled' data structure

Type	Variable Name	Remark
unsigned char	Bombs	boolean
unsigned char	Guns	boolean
unsigned char	Missiles	boolean

B.2.25 FWA Egress

same as Task "FWA Ingress".

B.2.26 FWA Return to Base

Table B.23 Task 'FWA Return to Base' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
unsigned char	NumPoints	Optional Return Route
tf_point *	PointAddr	
tf_location *	TargetLocation	
unsigned char	FlightMethod	Enumeration Type
float	FlightSpeed	
float	Altitude	
unsigned char	Formation	Enumeration Type
unsigned char	MissionType	Enumeration Type
unsigned char	ActionAfterMission	Enumeration Type

B.2.27 FWA Interdiction

Table B.24 Task 'FWA Interdiction' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	RouteToTarget
tf_point *	PointAddr	
unsigned char	NumPoints	OptionalReturnRoute
tf_point *	PointAddr	
tf_location *	TargetLocation	
unsigned char	FlightMethod	Enumeration Type
float	FlightSpeed	
float	Altitude	
unsigned char	Formation	Enumeration Type
unsigned char	MissionType	Enumeration Type
unsigned char	ActionAfterMission	Enumeration Type

B.2.28 RWA Fly Route

Table B.25 Task 'RWA Fly Route' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	Route
tf_point *	PointAddr	
float	Speed	
float	CatchUpSpeed	
float	Altitude	
unsigned char	Formation	Enumeration Type
unsigned char	Spacing	Enumeration Type
float	UserDefinedSpacing	
unsigned char	MovementType	Enumeration Type

unsigned char	TargetFacingMode	boolean
tf_location *	NapOfEarthTRP	

B.2.29 RWA Hover

Table B.26 Task 'RWA Hover' data structure

Type	Variable Name	Remark
tf_location *	FARPPoint	
float	Speed	
float	Altitude	
unsigned char	ActiveFuelFARP	boolean
unsigned char	ActiveAmmoFARP	boolean

B.2.30 RWA Orbit

Table B.27 Task 'RWA Orbit' data structure

Type	Variable Name	Remark
tf_location *	CenterPoint	
float	Radius	
float	Speed	
float	Altitude	

B.2.31 RWA Assemble

same as Task "RWA Orbit".

B.2.32 RWA Attack

Table B.28 Task 'RWA Attack' data structure

Type	Variable Name	Remark
tf_location *	Objective	
float	Speed	
unsigned char	AttackType	Enumeration Type

B.2.33 RWA Hasty Occupy Position

Table B.29 Task 'RWA Hasty Occupy Position' data structure

Type	Variable Name	Remark
unsigned char	NumPoints	BattlePosition
tf_point *	PointAddr	
tf_location *	LeftTRP	

tf_location *	RightTRP	
tf_location *	EnggAreaTRP	
unsigned char	TargetFacingMode	boolean
float	Speed	
float	Altitude	
float	AltitudeAtEnt	

B.3 Enumeration Type for Variables in Task

Task Kind	Variable Names	Field Value	
Assault	Secure Objective	0: No 1: Yes*	*: default value
	Formation	0 : Other	
		1 : Column	
		2 : Staggered-Column	
		3 : Echelon-Right	
		4 : Echelon-Left	
		5 : Line*	
		6 : Wedge

```

NAME
      SFT - Scenario File Translator

SYNOPSIS
      SFT [-help] [-N|n] [-C|c] [options]

DESCRIPTION
      SFT converts a scenario to another type of scenario. A
      scenario file that will be translated to another format
      is called 'source scenario', and a scenario file which
      is produced by SFT is 'target scenario'.

      A 'source simulation' is a computer simulation name
      which operates a source scenario, a 'target simulation'
      is a name of computer simulation which the target
      scenario will be run.

OPTIONS
      The following options are supported:

      -help
            Show the usage message.

      -N|n
            Show the corresponding numbers of each simulation

      -C|c
            SFT interactive with the user. SFT asks a source
            simulation type, a source scenario file name, a
            target simulation type and a target scenario file
            name.

      -s [number] [input]
            Name the source simulation name number and source
            scenario file. 'input' should have a correct
            directory path and file name.

      -t [number] [output]
            Name the target simulation name number and target
            scenario file. 'output' should have a correct
            directory path and file name.

OTHER NECESSARY INPUT
            When converting a source scenario to ModSAF scenario,
            Exercise ID and terrain file path/name are needed.

            Converting to EADSIM scenario file, laydown file name
            without suffix (.lay) is necessary.

If a source simulation is BATTLESIM, there can be several input files to build a scenario. Be sure all input files are ended with series of number from 0. In that case, input file to SFT is the first file name and the number of files is needed to convert to a target scenario.

EXAMPLES

SFT -s 1 ./data/scn.1 -t 2 ./data/scn.2

Convert a source scenario scn.1 of corresponding source simulation, which is located in ./data to a target scenario scn.2 of simulation number 2 into ./data directory.

<u>*Vita*</u>

Captain Heon-Gyu Park was born on April 7, 1966, in YaeGwan, GyungSangBukDo, Republic of Korea. He graduated from the Korea Military Academy with a Bachelor of Science degree in Computer Engineering in March 1988. After receiving his commission as an Army Infantry officer, he was a platoon leader at GOP (Guard of Post) near PanMunJom from 1988 through 1989. His next assignment was a leader officer of a guard of honor in the Third Army Headquarters. In 1991, after completing the Officer Basic Course (OBC) of Computer Engineering, he was assigned to the 1st Anti-Air Brigade as a Computer Engineer. There he led a team of computer software engineers and was responsible for maintaining all systems and the network. He remained in that position until May of 1994 when he was selected to attend the Air Force Institute of Technology at Wright-Patterson Air Force Base, Dayton Ohio to study for his Master of Science degree in Electrical and Computer Engineering. After completing his Masters degree, he will be assigned to the Headquarters of Army, Republic of Korea.

13. ABSTRACT *(Maximum 200 words)*

There exists a variety of simulation generation and analysis products which have differing purposes and functions designed to simulate a real military battlefield. Due to the particular purpose of each simulation, it is impractical to use one scenario of a simulation directly with another simulation without a translator since there is no standard scenario format. In the current environment, interoperability between simulations is becoming more important in large scale simulations and distributed exercises. The Scenario File Translator (SFT) provides an easy and accurate way to create a scenario from a heterogeneous simulation. The SFT can load and save the three research simulations: ModSAF, EADSIM, and BATTLESIM. It also defines the general transitional prototype (TP) which is the information most commonly used to create a mock battlefield computer simulation. Every source scenario is converted through TP for program extensibility and reusability. System functionality is accessible through a graphical user interface (GUI). Although this system was designed for three simulations, it can be applied to any other simulations by creating only two additional functions: one which maps the new scenario to the TP and another which remaps the TP into the transitional scenario protocol.
